

Towards a Proof of the Fourier–Entropy Conjecture?

Esty Kelman* Guy Kindler† Noam Lifshitz‡ Dor Minzer§ Muli Safra¶

Abstract

The total influence of a function is a central notion in analysis of Boolean functions, and characterizing functions that have small total influence is one of the most fundamental questions associated with it. The KKL theorem and the Friedgut junta theorem give a strong characterization of such functions whenever the bound on the total influence is $o(\log n)$. However, both results become useless when the total influence of the function is $\omega(\log n)$. The only case in which this logarithmic barrier has been broken for an interesting class of functions was proved by Bourgain and Kalai, who focused on functions that are symmetric under large enough subgroups of S_n .

In this paper, we build and improve on the techniques of the Bourgain–Kalai paper and establish new concentration results on the Fourier spectrum of Boolean functions with small total influence. Our results include:

1. A quantitative improvement of the Bourgain–Kalai result regarding the total influence of functions that are transitively symmetric.
2. A slightly weaker version of the Fourier–Entropy Conjecture of Friedgut and Kalai. Our result establishes new bounds on the Fourier entropy of a Boolean function f , as well as stronger bounds on the Fourier entropy of low-degree parts of f . In particular, it implies that the Fourier spectrum of a constant variance, Boolean function f is concentrated on $2^{O(I[f] \log I[f])}$ characters, improving an earlier result of Friedgut. Removing the $\log I[f]$ factor would essentially resolve the Fourier–Entropy Conjecture, as well as settle a conjecture of Mansour regarding the Fourier spectrum of polynomial size DNF formulas.

Our concentration result for the Fourier spectrum of functions with small total influence also has new implications in learning theory. More specifically, we conclude that the class of functions whose total influence is at most K is agnostically learnable in time $2^{O(K \log K)}$ using membership queries. Thus, the class of functions with total influence $O(\log n / \log \log n)$ is agnostically learnable in $\text{poly}(n)$ time.

1 Introduction

The field of Analysis of Boolean functions is by now an integral part of Theoretical Computer Science, Combinatorics and Probability. Many basic results, such as the KKL Theorem [18] and the various junta theorems [10, 5] have a wide range of applications including PCP constructions [16, 22, 9], metric non-embeddability results [23], Extremal Combinatorics [8, 21] and many more.

Perhaps the most basic, non-trivial, question in the field is to characterize functions that have small total influence. Throughout the paper, we will consider the Boolean hypercube $\{0, 1\}^n$ equipped with the uniform

measure,¹ and in particular Boolean functions defined over it, i.e. $f: \{0, 1\}^n \rightarrow \{0, 1\}$. The influence of the i th variable, $I_i[f]$, is the probability that $f(x) \neq f(x \oplus e_i)$ when we sample x according to the uniform distribution. The total influence of f is the sum of all individual influences, i.e. $I[f] = I_1[f] + \dots + I_n[f]$. What can be said about a function f with constant variance, that has small total influence, i.e. $I[f] \leq K$?

One obvious example of such functions are K -juntas, i.e. functions f that depend on at most K variables. Clearly, if f is a K -junta, then $I[f] \leq K$. A better example, known as the Tribes function, was given by Ben-Or and Linial [3], and it depends on $e^{\Omega(K)}$ variables, all of which have the same influences. The KKL Theorem and the Friedgut junta theorem state that in a sense, these are the worst possible examples. The KKL Theorem [18] asserts that in this case, there must be a variable i with a large individual influence of $e^{-O(K)}$. Friedgut [10] strengthened that result, showing that f in fact must essentially depend only on $e^{O(K)}$ variables. We note that these results are very effective when K is thought of as constant, and remain meaningful as long as $K \leq \varepsilon \log n$. When K is, say, $100 \log n$, these results become completely trivial – this is a well known barrier in analysis of Boolean functions, regarding which very little is known.

Sharp thresholds. Motivated by the study of sharp thresholds of graph properties, Bourgain and Kalai [6] studied the above question for functions $f: \{0, 1\}^n \rightarrow \{0, 1\}$ that are symmetric with respect to a subgroup $G \subseteq S_n$.² They showed that if the subgroup G is nice enough, then one has $I[f] = \omega(\log n)$ for all functions f symmetric under G . More precisely, for each $\varepsilon > 0$ and subgroup G , Bourgain and Kalai consider the parameter $a_\varepsilon(G)$, defined to be smallest possible d such that the orbit of each $S \subseteq [n]$ of size d is at least of size $e^{d^{1+\varepsilon}}$. Using this parameter, Bourgain and Kalai prove that $I[f] \geq C(\varepsilon)a_\varepsilon(G)\text{var}(f)$, for some $C(\varepsilon) > 0$. The class of subgroups for which this statement is useful includes symmetries of graphs, hypergraphs, $GL(n, \mathbb{F}_q)$ and more. The latter result played an important part in a recent result in coding theory, showing that Reed-Muller codes with constant rate achieve capacity over erasure channels with random errors [25] (though by now, an alternative argument that bypasses the use of Bourgain-Kalai is known [26]).

Learning theory. Proving strong structural results on Boolean functions with bounded total influence, say at most $100 \log n$, is often times useful in designing learning algorithms for specific concept classes, such as the class of polynomial size DNF formulas. In particular, it has long been known that a concept class in which each function can be approximated by a sparse polynomial is learnable with membership queries [12, 27]. More recently, it has been shown that such property is strong enough to imply learnability in the presence of some errors, i.e. in the agnostic learning model [14]. We elaborate on the topic and on our results along these lines in Section 1.3.1.

Percolation. Another motivation to develop tools bypassing the logarithmic barrier comes from percolation theory. Kalai [19] asked whether there is a variant of the Bourgain-Kalai Theorem in which the symmetry condition is relaxed to a weaker notion of regularity. His question was motivated by a problem in percolation theory, in which one has a sequence of function f_n (which is the indicator of the crossing event in the 3-dimensional grid at the critical probability) and the goal is to prove good lower bounds on the total influence of f_n . More precisely, the goal is to prove that for every n one has $I[f_n] \geq a_n > 0$, where the sequence a_n satisfies that $\sum_{n=1}^{\infty} \frac{1}{na_n}$ converges (i.e. morally that a_n is slightly larger than $\log n$). The class of

¹Many of the statements we give have natural analogs for the p -biased measure.

²We say f is symmetric under a permutation $\pi \in S$, if $f(x) = f(\pi(x))$ for all $x \in \{0, 1\}^n$, where $\pi(x)_i = x_{\pi(i)}$. We say f is symmetric under a set of permutations $G \subseteq S_n$ if it is symmetric under each $\pi \in G$.

functions f_n , however, does not have the symmetries required for the Bourgain-Kalai Theorem.

Our main result can be viewed as a variant of the Bourgain-Kalai Theorem that relaxes the symmetry condition, and we prove it is enough that all low Fourier coefficients of f are small.

1.1 The Fourier–Entropy Conjecture

Another form of structural results on Boolean functions with $I[f] \leq K$ one may hope for, is that of concentration of the Fourier Spectrum only on a small number of characters. In other words, can we say that except for a negligible mass, all Fourier weight of f is concentrated on few Fourier coefficients? Friedgut’s theorem [10] (or rather, its proof) implies that except for negligible amount of mass, all Fourier weight of f lies on at most $e^{O(K^2)}$ Fourier coefficients; in general, this is the best bound known to date. Friedgut and Kalai [11] conjectured that the actual answer should be $e^{O(K)}$; in fact, they propose the more refined *Fourier–Entropy Conjecture*, stating that the Shannon-Entropy of the Fourier spectrum of a Boolean function (thought of as a distribution) is at most $O(I[f])$. Here, the Fourier entropy of a function f is given by $H[\hat{f}] = \sum_{S \subseteq [n]} \hat{f}(S)^2 \log(1/\hat{f}(S)^2)$. Despite significant efforts, progress towards the Fourier–Entropy Conjecture has been slow, and it has been proved only for special classes of functions [7, 24, 30, 31, 33].

The min-entropy of the Fourier Spectrum of a function f is defined by $H_\infty[\hat{f}] = \min_S \log(1/\hat{f}(S)^2)$. The Fourier–Min–Entropy Conjecture is a relaxation of the Fourier–Entropy Conjecture, stating that min-entropy of the Fourier spectrum of a Boolean function is at most $O(I[f])$. As the min-entropy of a distribution is always upper bounded by the Shannon-Entropy of a distribution, one sees that this conjecture is strictly weaker. O’Donnell noted that for monotone functions (and more generally for unate functions), this conjecture follows immediately from the KKL Theorem (while the Fourier–Entropy Conjecture is not known for monotone functions).³ Progress towards this conjecture has also been slow [1, 32].

1.2 Main results

Our main results are new bounds on the Fourier min-entropy and the Fourier entropy of a Boolean function $f: \{0, 1\}^n \rightarrow \{0, 1\}$. It will be convenient to state them in terms of the normalized total influence of f , i.e. $\tilde{I}[f] = \frac{I[f]}{\text{var}(f)}$. First, we show that the Fourier min-entropy Conjecture holds up to poly-logarithmic factor in $\tilde{I}[f]$.

Theorem 1.1. *There is $C > 0$, such that for any function $f: \{0, 1\}^n \rightarrow \{0, 1\}$ there is a non-empty $S \subseteq [n]$ of size $O(\tilde{I}[f])$ such that $|\hat{f}(S)| \geq 2^{-C \cdot |S| \log(1 + \tilde{I}[f])} \sqrt{\text{var}(f)}$. In particular,*

$$H_\infty[f] \leq O\left(\tilde{I}[f] \log(1 + \tilde{I}[f])\right).$$

Our result is in fact stronger in several ways. First, we show that not only there exists a significant Fourier coefficient for f , but in fact almost all the Fourier mass of f lies on such characters.

Theorem 1.2. *For every $\eta > 0$, there exists $C > 0$, such that for all $f: \{0, 1\}^n \rightarrow \{0, 1\}$ we have*

$$\sum_S \hat{f}(S)^2 1_{|\hat{f}(S)| \leq 2^{-C \cdot \tilde{I}[f] \log(1 + \tilde{I}[f])}} \leq \eta \cdot \text{var}(f). \quad (1)$$

³A function $f: \{0, 1\}^n \rightarrow \{0, 1\}$ is said to be increasing (respectively decreasing) with respect to coordinate i , if for every $x \in \{0, 1\}^n$ with $x_i = 0$, it holds that $f(x \oplus e_i) \geq f(x)$ (respectively $f(x \oplus e_i) \leq f(x)$). The function f is called monotone if it is increasing along each $i \in [n]$, and called unate if along each $i \in [n]$ it is either increasing or decreasing.

Second, we show that a slightly weaker version of the Fourier–Entropy Conjecture holds for the low-degree parts of f . Here, the part of f of degree at most d is denoted by $f^{\leq d}$ and is defined to be the part of the Fourier transform of f up to degree d (see Section 2 for a formal definition).

Theorem 1.3. *There exists an absolute constant $K > 0$, such that for any $D \in \mathbb{N}$ and $f: \{0, 1\}^n \rightarrow \{0, 1\}$ we have that*

$$H[\widehat{f^{\leq D}}] \leq K \sum_{|S| \leq D} |S| \log(|S| + 1) \widehat{f}(S)^2 + K \cdot I[f].$$

Note that as $I[f] = \sum_S |S| \widehat{f}(S)^2$, Theorem 1.3 just falls short of proving the Fourier entropy conjecture by a factor of $\log(|S|)$. In the worst case, this factor may be as large as $\log(\deg(f))$, however for most interesting functions the contribution of this logarithmic factor is typically much smaller. We also note that a particularly interesting setting of D is $D = 100 \cdot I[f]$, since most of the Fourier mass of f lies on characters S such that $|S| \leq D$ and then the logarithmic factor contributes at most $\log(D)$.

The above results follow from our main technical result, Corollary 6.7, which may be of independent interest. We remark that this project began with the goal of gaining a better understanding of the (notoriously hard) Bourgain–Kalai paper, and explore the underlying idea that allowed them to bypass the logarithmic barrier. Indeed, our proofs build and improve upon the ideas of Bourgain and Kalai, and in our view are also considerably simpler. The core idea of the argument now boils down to a general statement that upper bounds inner products $\langle f, g \rangle$ for a Boolean function f and a real-valued, low-degree function g , by their Fourier coefficients, total influences and norms. This result could be thought of a successive series of inequalities that improve each other, the first one of which is the KKL Theorem, and the proof of each inequality uses the previous inequalities (formally, by induction). We defer a more detailed discussion of our techniques and proofs to Section 4.1.

Remark 1.4. *One can establish variants of Theorems 1.1, 1.2 and 1.3 for general real-valued functions $f: \{0, 1\}^n \rightarrow \mathbb{R}$. The proof goes along the same lines, except that the quantity $I[f, g]$ considered throughout the proof is redefined to be $I[f, g] = \sum_{i=1}^n \|\partial_i f\|_2^{1/4} \|\partial f\|_{4/3}^{1/2} \|\partial_i g\|_2$.*

1.3 Applications

1.3.1 Learning Theory

The Fourier–Entropy Conjecture is closely related to the problem of learning functions in the membership model. Intuitively, if a function has small Fourier Entropy, that means that its Fourier transform is concentrated on a few characters. In other words, it means that the function can be approximated by a sparse polynomial, a class that is very important in the context of learning theory.

It is well-known that the class of functions approximated by sparse polynomials is learnable using membership queries [12, 27]. However, one may wonder if this class is learnable in the more challenging model of agnostic learning.

The framework of agnostic learning was defined by Kearns et al.[20], who proposed it as a more realistic version of the PAC-learning model. Indeed, it is aimed at capturing the intuition that often in the task of learning a function, the data we see is in fact a noisy version of the actual data in the real world, and therefore one cannot make very strong structural assumptions on it, but rather that it is close to a very structured object. We formalize this notion next.

A notable example in this context is the class of polynomials-size DNF formulas, which is known to be somewhat sparse (its Fourier spectrum is concentrated on at most on at most $n^{O(\log \log n)}$ characters) but not enough

Let $f: \{0, 1\}^n \rightarrow \{0, 1\}$ be an *arbitrary* Boolean function and let $\mathcal{C} \subset \{g \mid g: \{0, 1\}^n \rightarrow \{0, 1\}\}$ be a concept class. Define $\text{opt}_{\mathcal{C}}(f) = \min_{c \in \mathcal{C}} \Pr_{x \in \{0, 1\}^n} [c(x) \neq f(x)]$, i.e. the distance of f from the concept class \mathcal{C} .

Definition 1.5. We say that \mathcal{C} is agnostically learnable with queries with respect to the uniform distribution, if there exists a randomized algorithm that given black box access to any f , runs in time $\text{poly}(n, \varepsilon^{-1}, \log \frac{1}{\delta})$ and outputs a hypothesis h such that $\Pr_{x \in \{0, 1\}^n} [h(x) \neq f(x)] \leq \text{opt}_{\mathcal{C}}(f) + \varepsilon$ with probability $1 - \delta$.

Golpalan et al.[14] showed that every concept class that has sparse approximation is agnostically learnable (the running time depends on the sparsity of the approximation and other parameters).

Theorem 1.6 ([14], Theorem 16). *Let $t, \varepsilon > 0$ and suppose \mathcal{C} is a concept class such that for every $c \in \mathcal{C}$, there exists a $p: \{0, 1\}^n \rightarrow \mathbb{R}$ such that*

1. *The polynomial p is t -sparse, i.e. $\sum_S |\widehat{p}(S)| \leq t$.*
2. *The polynomial p approximates c in ℓ_1 : $\mathbb{E}_{x \in \{0, 1\}^n} [|p(x) - c(x)|] \leq \varepsilon$.*

Then there exists a agnostic learning algorithm for \mathcal{C} that runs in time $\text{poly}(t, \frac{1}{\varepsilon}, n)$.

Combining this result with Theorem 1.2, we get the following corollary.

Corollary 1.7. *For every $\varepsilon > 0$ and $K \in \mathbb{N}$, the concept class \mathcal{C} of functions whose total influence is at most K is agnostically learnable in time $\text{poly}(2^{O_\varepsilon(K \log K)}, \frac{1}{\varepsilon}, n)$*

Indeed, given $\varepsilon > 0$ we apply Theorem 1.2 with $\eta = \varepsilon^2$, and get the Fourier mass of f outside

$$\mathcal{S} = \left\{ S \mid \left| \widehat{f}(S) \right| \geq 2^{-CK \log K} \right\}$$

is at most ε^2 , for some C depending on ε . Therefore the polynomial $p(x) = \sum_{S \in \mathcal{S}} \widehat{f}(S) \chi_S(x)$ is close to f in ℓ_2 , i.e. $\|f - p\|_2 \leq \varepsilon$, and in particular $\|f - p\|_1 \leq \varepsilon$. Secondly, since the sum of squares of Fourier coefficients of f is at most 1, we have that $|\mathcal{S}| \leq 2^{2CK \log K}$, and in particular p is t -sparse for $t = 2^{2CK \log K}$.

Corollary 1.7 implies that as far as polynomial time algorithms are concerned, one can agnostically learn the concept class of functions whose total influence is $O\left(\frac{\log n}{\log \log n}\right)$. This just falls short of capturing the class of polynomial size DNF formulas, which is known to be contained in the class of functions with total influence $O(\log n)$. We remark that while learning algorithms for the class of polynomial size DNF's are known [17], no agnostic learner is known. Proving the Fourier Entropy Conjecture is a known avenue towards achieving this goal [13], and we believe this avenue to be promising in light of our results. More concretely, to achieve this goal it would be enough to “shave off” the logarithmic factor from Theorem 1.2 (which would also establish a conjecture of Mansour [28]).

1.3.2 Sharp thresholds

Theorem 1.1 can be used to prove a quantitatively improved, nearly tight Bourgain-Kalai-like Theorem. For example, it implies that graph properties with constant variance have total influence at least $\Omega\left(\frac{\log^2 n}{(\log \log n)^2}\right)$. It is also strong enough to imply polynomial lower bound on the total influence of a function f , provided its group symmetries is large enough. See Section 7.4 for more details.

Organization. In Section 2 we give standard tools and notions from discrete Fourier analysis. In Section 3 we present two important ideas that are used in the proof of our main results. In Section 4 we state and prove a basic version of our main technical result, Theorem 4.1 and Corollary 4.2. In Section 5 we give a first improvement over Theorem 4.1, namely Theorem 5.2 and Corollary 5.4, and in Section 6 we give a further improvement of that result, namely Theorem 6.6 and Corollary 6.7 Finally, in Section 7 we deduce several corollaries, including Theorems 1.1, 1.2 and 1.3.

2 Preliminaries

In this section we describe the basics of Fourier analysis over the hypercube that will be needed in this paper (see [29] for a more systematic treatment).

Notations. We denote $[n] = \{1, \dots, n\}$. Throughout the paper, $\log x$ is the natural logarithm of x .

2.1 Fourier analysis on the hypercube

Consider the hypercube $\{0, 1\}^n$ along with the uniform measure μ , and consider real-valued functions $f: \{0, 1\}^n \rightarrow \mathbb{R}$ equipped with the inner product $\langle f, g \rangle = \mathbb{E}_{x \sim \mu} [f(x)g(x)]$. The set $\{\chi_S\}_{S \subseteq [n]}$, where $\chi_S = (-1)^{\sum_{i \in S} x_i}$ is the well-known Fourier basis that forms an orthonormal basis with respect to our inner product, thus one can expand any $f: \{0, 1\}^n \rightarrow \mathbb{R}$ as

$$f(x) = \sum_{S \subseteq [n]} \widehat{f}(S) \chi_S(x), \quad \text{where } \widehat{f}(S) = \langle f, \chi_S \rangle.$$

The degree of a function f is $\deg(f) = \max_{S: \widehat{f}(S) \neq 0} |S|$. Since $\{\chi_S\}$ is an orthogonal system, we have the Parseval/ Plancherel equality.

Fact 2.1. For any $f, g: \{0, 1\}^n \rightarrow \mathbb{R}$ we have that $\langle f, g \rangle = \sum_{S \subseteq [n]} \widehat{f}(S) \widehat{g}(S)$.

2.2 Restrictions, derivatives and influences

Given a function $f: \{0, 1\}^n \rightarrow \mathbb{R}$, a set of variables $S \subseteq [n]$ and $z \in \{0, 1\}^S$, the restricted function $f_{S \rightarrow z}$ is the function from $\{0, 1\}^{[n] \setminus S}$ to \mathbb{R} resulting from fixing S 's coordinates in x to be z . If S is a singleton $\{i\}$, we will denote this restriction by $f_{i \rightarrow z}$.

Definition 2.2. The discrete derivative of $f: \{0, 1\}^n \rightarrow \mathbb{R}$ in direction i is a function $\partial_i f: \{0, 1\}^{n \setminus \{i\}} \rightarrow \mathbb{R}$ defined by $\partial_i f(x) = \frac{1}{2}(f_{i \rightarrow 0}(x) - f_{i \rightarrow 1}(x))$.

More generally, for a set of variables $T \subseteq [n]$, the derivative of f with respect to T is $\partial_T f: \{0, 1\}^{[n] \setminus T} \rightarrow \mathbb{R}$ is defined by iteratively applying the derivative operator on f for each $i \in T$. Alternatively,

$$\partial_T f(x) = 2^{-|T|} \sum_{z \in \{0, 1\}^T} (-1)^{|z|} f_{T \rightarrow z}(x).$$

The Fourier expansion of $\partial_T f(x)$ is $\sum_{S \supseteq T} \widehat{f}(S) \chi_{S \setminus T}(x)$.

The following definition generalizes the notion of influences to real-valued functions. We remark that for Boolean functions, it differs by a factor of 4 from the definition given in the introduction (this is done only for convenience).

Definition 2.3. Let $f: \{0, 1\}^n \rightarrow \mathbb{R}$ be a function. The influence of a variable $i \in [n]$ is given by $I_i[f] = \|\partial_i f\|_2^2$, and the total influence of f is defined to be $I[f] = \sum_{i=1}^n I_i[f]$.

The generalized influence of a set $S \subseteq [n]$ on $f: \{0, 1\}^n \rightarrow \mathbb{R}$ is $I_S[f] = \|\partial_S f\|_2^2$.

Using the Fourier expression for $\partial_T f$ and Parseval, we see that $I_T[f] = \sum_{S \supseteq T} \widehat{f}(S)^2$. In particular, using this formula for T 's that are singletons and summing, one gets that the total influences of f can be written as $I[f] = \sum_S |S| \widehat{f}(S)^2$.

Low-degree part and low-degree influences. For $f: \{0, 1\}^n \rightarrow \mathbb{R}$ and $d \leq n$, we define the degree at most d part of f , $f^{\leq d}$, to be

$$f^{\leq d}(x) = \sum_{|S| \leq d} \widehat{f}(S) \chi_S(x).$$

Using the Fourier formula for the total influence and Parseval, one sees that $I[f^{\leq d}] \leq d \|f\|_2^2$, and hence there are at most $\frac{d}{\tau}$ variables i that have $I_i[f^{\leq d}] \geq \tau \|f\|_2^2$. A similar property holds for generalized low-degree influences of f .

Fact 2.4. For any $v \leq d$ and $f: \{0, 1\}^n \rightarrow \mathbb{R}$, one has that $\sum_{|T| \leq v} I_T[f^{\leq d}] \leq 2d^v \|f\|_2^2$.

Proof. Using the Fourier formula for $I_S[f^{\leq d}]$, the left hand side is equal to

$$\sum_{|T| \leq v} I_T[f^{\leq d}] = \sum_{|T| \leq v} \sum_{\substack{|S| \leq d \\ S \supseteq T}} \widehat{f}(S)^2 = \sum_{|S| \leq d} \widehat{f}(S)^2 \sum_{\substack{T \subseteq S \\ |T| \leq v}} 1.$$

Fix S . The inner summation is equal to the number of subsets of S of size at most v , hence it is equal to $\binom{|S|}{0} + \dots + \binom{|S|}{\min(v, |S|)} \leq \sum_{k=0}^v \frac{|S|^k}{k!}$. If $v \leq 1$, then this sum is at most $2d^v$, and if $v > 1$, we may upper bound the sum by $1 + d + \sum_{k=2}^v \frac{|S|^k}{k!} \leq 1 + d + d^v \sum_{k=2}^{\infty} \frac{1}{k!} = 1 + d + d^v(e - 2) \leq 2d^v$. \square

2.3 Random restrictions

Let $f: \{0, 1\}^n \rightarrow \mathbb{R}$ be a function, and $I \subseteq [n]$. A random restriction of f on I is the function $f_{I \rightarrow z}$ where we sample z uniformly from $\{0, 1\}^I$. In our applications we will usually have two functions, $f, g: \{0, 1\}^n \rightarrow \mathbb{R}$ and we will consider the effect of the same random restriction of them. For example, it is easy to show that for any $I \subseteq [n]$, the expected inner product of $\langle f_{I \rightarrow z}, g_{I \rightarrow z} \rangle$ over $z \in_R \{0, 1\}^I$ is equal to $\langle f, g \rangle$. Another quantity associated with f, g that we will consider is the cross-total-influence.

Definition 2.5. For any $f, g: \{0, 1\}^n \rightarrow \mathbb{R}$ and $i \in [n]$, we define the cross-influence along direction i to be $I_i[f, g] = \sqrt{I_i[f]I_i[g]}$. The cross-total-influence of f, g is given by $I[f, g] = \sum_{i=1}^n I_i[f, g]$.

By Cauchy-Schwarz, one always has that $I[f, g] \leq \sqrt{I[f]I[g]}$. The quantity $I[f, g]$ though will be easier for us to work with inductively, and the following property will be useful for us.

Lemma 2.6. For any $f, g: \{0, 1\}^n \rightarrow \mathbb{R}$ and $I \subseteq [n]$, we have that

$$\mathbb{E}_{z \in \{0,1\}^I} [I[f_{I \rightarrow z}, g_{I \rightarrow z}]] \leq \sum_{i \notin I} I_i[f, g].$$

Proof. By definition, the left hand side is equal to

$$\begin{aligned} \mathbb{E}_{z \in \{0,1\}^I} \left[\sum_{i \in \bar{I}} \sqrt{I_i[f_{I \rightarrow z}]} \cdot \sqrt{I_i[g_{I \rightarrow z}]} \right] &= \sum_{i \in \bar{I}} \mathbb{E}_{z \in \{0,1\}^I} \left[\sqrt{I_i[f_{I \rightarrow z}]} \cdot \sqrt{I_i[g_{I \rightarrow z}]} \right] \\ &\leq \sum_{i \in \bar{I}} \sqrt{\mathbb{E}_{z \in \{0,1\}^I} [I_i[f_{I \rightarrow z}]]} \cdot \sqrt{\mathbb{E}_{z \in \{0,1\}^I} [I_i[g_{I \rightarrow z}]]} \\ &= \sum_{i \in \bar{I}} \sqrt{I_i[f]} \sqrt{I_i[g]}, \end{aligned}$$

where the second transition is by Cauchy-Schwarz. □

We will also need the following fact about Fourier coefficients of random restrictions.

Lemma 2.7. For any $g: \{0, 1\}^n \rightarrow \mathbb{R}$, $I \subseteq [n]$ and $S \subseteq I$ we have that

$$\mathbb{E}_{z \in \{0,1\}^I} [\widehat{g_{J \rightarrow z}}(S)^2] = \sum_{T: T \cap I = S} \widehat{g}(T)^2.$$

Proof. The Fourier coefficient of S in $g_{J \rightarrow z}$ is $\sum_{T \subseteq \bar{I}} \widehat{g}(S \cup T) \chi_T(z)$. Thinking of the latter as a function of z and using Parseval's equality, we get that the expectation of its square is equal to $\sum_{T \subseteq \bar{I}} \widehat{g}(S \cup T)^2$. □

2.4 Hypercontractivity

We will need the hypercontractive inequality [2, 4, 15], which states that for $q \geq 2$, the q -norm and 2-norm of degree- d functions is comparable up to exponential factor in d .

Theorem 2.8. If $f: \{0, 1\}^n \rightarrow \mathbb{R}$ is a function of degree at most d , and $q \geq 2$, then $\|f\|_q \leq (q-1)^{d/2} \|f\|_2$.

3 Restrictions, partitions and degree reductions

In this section we state several lemmas that will be helpful in the proof of Theorem 1.1, and we start by describing the basic motivation.

Using hypercontractivity (Theorem 2.8) incurs a loss of exponential factor in the degree of the function it is applied on. This exponential-factor loss is in fact the bottleneck in KKL and Friedgut's Theorems. It is ultimately the reason it is hard to bypass the logarithmic barrier. Therefore one may search for methods by which the degree of a function could be reduced prior to applying hypercontractivity.

One natural idea is to consider random restrictions: if we pick $I \subseteq [n]$ randomly by including each element with probability $\frac{1}{2}$ in it and restrict variables outside I , then the degree of f shrinks by a factor of 2 – at least if we are willing to discard characters of small total mass from it. Another point that is often

useful, is that this allows one to view the given function f as $f(y, z)$, where $y \in \{0, 1\}^I$, $z \in \{0, 1\}^{\bar{I}}$ and the degree of f on each one of y, z (separately) is at most $d/2$.

Sometimes, it is necessary to get a degree reduction by more than a constant factor. One can certainly decrease the size of the set of live variables I , however this introduces asymmetry between I and \bar{I} , and thus we may not enjoy any reduction on \bar{I} . The idea of *random partition* remedies this situation. To get a degree reduction by factor m , we may consider a random partition of $[n]$ into m disjoint sets, i.e. $[n] = I_1 \cup \dots \cup I_m$ generated by including every $i \in [n]$ in each one of them with equal probability. We show that under mild conditions on d and m , given a function f there is a partition of $[n]$ into m parts and a function f' close to f in ℓ_2 , such that the restrictions of f' to each one of the parts, $(f')_{\bar{I}_j \rightarrow z}$, is of degree (roughly) at most d/m .

3.1 Random partitions

Recall that a function $f: \{0, 1\}^n \rightarrow \mathbb{R}$ is called degree- d homogenous if all Fourier characters in its support have size exactly d , and we would like to generalize it to functions that are “almost” degree d -homogenous. We say that $S \subseteq [n]$ is of size d within factor α if $\alpha d \leq |S| \leq d$, and often write it succinctly by $|S| \sim d$ (α will be clear from the context).

Definition 3.1. A function $f: \{0, 1\}^n \rightarrow \mathbb{R}$ is called (α, d) -almost-homogenous if all Fourier characters χ_S in its support satisfy $\alpha d \leq |S| \leq d$.

Definition 3.2. A partition of $[n]$ into m parts is $\mathcal{I} = (I_1, \dots, I_m)$, where I_1, \dots, I_m are pairwise disjoint sets that cover $[n]$.

As discussed earlier, a random partition into m parts is constructed by starting out with $I_1 = \dots = I_m = \emptyset$, and then for each $i \in [n]$ choosing the part I_j to which we add i uniformly among the m -parts.

The following claim asserts that if S is of size roughly d , and we choose a random partition \mathcal{I} , then with high probability $|S \cap I_j|$ is roughly of size d/m for all $j \in [m]$ (for technical reasons, since the definition of “almost-homogenous” allows for α to enter only in the lower bound on S , we allow for a slack of $(1 + \varepsilon)$ factor in the size too).

Lemma 3.3. Let $m, d \in \mathbb{N}$ and $\varepsilon, \alpha \in (0, 1)$. If $S \subseteq [n]$ is of size d within factor α , then

$$\Pr_{\mathcal{I}=(I_1, \dots, I_m)} [S \cap I_j \text{ is of size } (1 + \varepsilon)d/m \text{ within factor } (1 - 2\varepsilon)\alpha] \geq 1 - 2e^{-\frac{\varepsilon^2 |S|}{3m}}.$$

Proof. Let $\mathcal{I} = (I_1, \dots, I_m)$ be a random partition of $[n]$ into m parts, and for each $i \in [n]$ and $j \in [m]$ denote by $\mathbb{1}_{i \in I_j}$ the indicator function of the event that i is in I_j . Thus, for each $j \in [m]$ we may write the random variable $|S \cap I_j|$ as a sum of independent random variables $\sum_{i \in S} \mathbb{1}_{i \in I_j}$. Note that by linearity of expectation, we have that its expectation is $|S|/m$, and we use Chernoff’s bound to argue it is close to its expectation with high probability.

More precisely, using Chernoff’s inequality for indicator random variables we have that

$$\Pr_{\mathcal{I}} \left[\left| |S \cap I_j| - \frac{|S|}{m} \right| \geq \varepsilon \frac{|S|}{m} \right] \leq 2e^{-\frac{\varepsilon^2 |S|}{3m}},$$

and therefore by the Union Bound the probability $\left| |S \cap I_j| - \frac{|S|}{m} \right| \geq \varepsilon \frac{|S|}{m}$ for some $j \in [m]$ is at most m times that. \square

Next, we use the above lemma to prove that if f is almost d -homogenous, and we take a random partition \mathcal{I} , then on each one of the parts I_j , f is almost d/m -homogenous, provided we are willing to discard characters of small total mass from the Fourier transform of f .

More formally, let $\alpha, \varepsilon \in (0, 1)$ and $d \in \mathbb{N}$ be parameters, and let $\mathcal{I} = (I_1, \dots, I_m)$ be a partition of $[n]$. We denote by $G(\mathcal{I})$ the set of all $S \subseteq [n]$ such that $|S| \sim d$, and $S \cap I_j$ is of size $(1 + \varepsilon)d/m$ within factor $(1 - 2\varepsilon)\alpha$ for all $j \in [m]$. In this language, the previous lemma states that provided that d is large enough in comparison to m , for each S of size d within factor α we have that $\Pr_{\mathcal{I}}[S \in G(\mathcal{I})]$ is close to 1.

Corollary 3.4. *Let $m, d \in \mathbb{N}$, $\alpha, \varepsilon \in (0, 1)$, and let $f, g: \{0, 1\}^n \rightarrow \mathbb{R}$ be functions such that g is (α, d) -almost-homogenous. Then there is a partition $\mathcal{I} = (I_1, \dots, I_m)$ such that*

$$\sum_{S \in G(\mathcal{I})} |\widehat{f}(S)\widehat{g}(S)| \geq \left(1 - 2me^{-\frac{\varepsilon^2 \alpha d}{3m}}\right) \sum_{S \subseteq [n]} |\widehat{f}(S)\widehat{g}(S)|.$$

Proof. We choose a partition \mathcal{I} randomly, and lower bound the expectation of the right hand side. Let $\mathbb{1}_{S \in G(\mathcal{I})}$ be the indicator random variable of S being in $G(\mathcal{I})$. By Lemma 3.3, we have $\mathbb{E}[\mathbb{1}_{S \in G(\mathcal{I})}] \geq 1 - 2me^{-\frac{\varepsilon^2 \alpha d}{3m}}$ for each S in the support of \widehat{g} , and therefore

$$\mathbb{E}_{\mathcal{I}} \left[\sum_{S \in G(\mathcal{I})} |\widehat{f}(S)\widehat{g}(S)| \right] = \sum_{S \subseteq [n]} |\widehat{f}(S)\widehat{g}(S)| \mathbb{E}_{\mathcal{I}}[\mathbb{1}_{S \in G(\mathcal{I})}] \geq \left(1 - 2me^{-\frac{\varepsilon^2 \alpha d}{2m}}\right) \sum_{S \subseteq [n]} |\widehat{f}(S)\widehat{g}(S)|.$$

In particular, there exists a choice of \mathcal{I} for which the expression under the expectation on the left hand side is at least the right hand side. \square

3.2 Exchanging maximums and expectations

We next discuss a tool that goes in handy with partitions. Let $f: \{0, 1\}^n \rightarrow \mathbb{R}$, let $I \subseteq [n]$ and consider the Fourier coefficients of the restricted function, i.e. for each $S \subseteq I$ consider $h_S: \{0, 1\}^I \rightarrow \mathbb{R}$ defined by $h_S(x) = \widehat{f_{I \rightarrow x}}(S)$. Recall that we are using restrictions (or more generally partitions) as a way to decrease the degree of the function, but eventually we want to transfer the information we got on the restrictions back to information about f . For example, if the bound we proved involves 2-norms of the Fourier coefficients of the restrictions, i.e. of h_S 's, then a corresponding bound using Fourier coefficients of f can be established by Lemma 2.7. The bound however could depend on the functions h_S in a more involved way, e.g. on other ℓ_p -norms of them, in which case one can often get effective bounds using hypercontractivity.

Since we are interested in the min-entropy of a function f (e.g. for Theorem 1.1), we will naturally wish to understand the maximum Fourier coefficient after restriction as a function of x , $\max_S h_S(x)$, and relate it to some parameters of f . We do that in Lemma 3.5.

Generalizing the above discussion, let $h_1, \dots, h_k: \{0, 1\}^n \rightarrow \mathbb{R}$ be functions of low-degree, and consider the following two quantities. The first one is $\mathbb{E}_{x \sim \mu} \max_i h_i(x)^2$, and in the second quantity we interchange the order of these two operations, i.e. $\max_i \mathbb{E}_{x \sim \mu} h_i(x)^2$. Note that for every x and j we have that $\max_i h_i(x)^2 \geq h_j(x)^2$. Taking an expectation of this inequality over $x \sim \mu$, and then maximum over j establishes that the first quantity is always larger than the second quantity. The following lemma asserts that these two quantities are polynomially related, provided that the expected value of $\sum_{i=1}^k h_i(x)^2$ is constant.

Lemma 3.5. *If $h_1, h_2, \dots, h_k: \{0, 1\}^n \rightarrow \mathbb{R}$ are all of degree at most d , then*

$$\mathbb{E}_x \left[\max_{i \in [k]} h_i(x)^2 \right] \leq 3^d \max_{i \in [k]} \|h_i\|_2 \left(\mathbb{E}_x \left[\sum_{i=1}^k h_i(x)^2 \right] \right)^{1/2}.$$

Proof. Note that for all x , we have that $\max_{i \in [k]} h_i(x)^2 \leq \left(\sum_{i=1}^k h_i(x)^4 \right)^{1/2}$, and it will be more convenient for us to upper bound the expectation of the latter function. By Jensen's inequality, its expectation is at most

$$\left(\mathbb{E}_x \left[\sum_{i=1}^k h_i(x)^4 \right] \right)^{\frac{1}{2}} = \left(\sum_{i=1}^k \mathbb{E}_x [h_i(x)^4] \right)^{\frac{1}{2}}. \quad (2)$$

Using Theorem 2.8, we may upper bound $\mathbb{E}_x [h_i(x)^4]$ by $9^d \cdot \mathbb{E}_x [h_i(x)^2]^2$, and thus

$$(2) \leq 3^d \left(\sum_{i \in [k]} \mathbb{E}_x [h_i(x)^2]^2 \right)^{\frac{1}{2}} \leq 3^d \left(\max_{i \in [k]} \mathbb{E}_x [h_i(x)^2] \sum_{i \in [k]} \mathbb{E}_x [h_i(x)^2] \right)^{\frac{1}{2}},$$

and using the definition of 2-norm completes the proof. \square

4 A basic version of our main technical result

In this section, we state and prove Theorem 4.1 and Corollary 4.2, which are basic, less quantitatively efficient forms of our main technical result. We find it natural though to present them along with the slightly more natural argument, and encourage the reader to read this section before moving on to Section 5.

4.1 Proof idea

Before we prove (or even state) our main technical result, we begin with an informal overview of the idea. We start with presenting the (one-line) proof of the KKL Theorem. Let $f: \{0, 1\}^n \rightarrow \{0, 1\}$, $d \in \mathbb{N}$, and $g = f^{\leq d} - \widehat{f}(\emptyset)$; we have that:

$$\begin{aligned} \langle f, g \rangle &\leq \sum_{i=1}^n \langle \partial_i f, \partial_i (f^{\leq d}) \rangle \leq \sum_{i=1}^n \|\partial_i f\|_{4/3} \|\partial_i (f^{\leq d})\|_4 \leq \sqrt{3}^d \sum_{i=1}^n \|\partial_i f\|_{4/3} \|\partial_i (f^{\leq d})\|_2 \\ &\leq 2\sqrt{3}^d I[f] \max_i I_i[f^{\leq d}]^{1/4}, \end{aligned}$$

where in the second inequality we used Hölder's inequality and in the third inequality we used Theorem 2.8. In the last inequality, we upper bounded $\|\partial_i (f^{\leq d})\|_2$ by $\|\partial_i f\|_2^{1/2} \cdot \|\partial_i (f^{\leq d})\|_2^{1/2} = I_i[f]^{1/4} \|\partial_i (f^{\leq d})\|_2^{1/2}$, and used the Booleanity of f to bound $\|\partial_i f\|_{4/3} \leq 2I_i[f]^{3/4}$. Hence, this inequality gives us very good bounds on the weight f has on its low-degrees, provided that all of its low degree influences are small. This raises two questions:

1. What bounds could be proved if we know that there are only few influential variables?

2. Can we improve on this bound if we know stronger information about f , e.g. that its generalized low-degree influences, $I_S[f^{\leq d}]$, are all very small?

For the first question, a standard bound proceeds by handling characters S that consist only of influential variables separately (similar to Lemma 4.3 below). In essence, the bound says that if there are at most T variables with influence at least δ , then there are at most T^d characters consisting only of these influential variables, and one gets the bound $T^d \max_S \left| \widehat{f}(S)\widehat{g}(S) \right| + \sqrt{3}^d I[f]\delta^{1/4}$, which in this case is just

$$T^d \max_S \widehat{f}(S)^2 + \sqrt{3}^d I[f]\delta^{1/4}. \quad (3)$$

The second question is more interesting, and the obvious naive attempt one may first have quickly fails.⁴ One key insight in [6], is that a better way to use the information on generalized influence is by relating them to Fourier coefficients of random restrictions (and importantly, to something slightly stronger, see Lemma 2.7). For a function $f: \{0, 1\}^n \rightarrow \{0, 1\}$, a set $I \subseteq [n]$ and a subset $S \subseteq I$, the expected Fourier coefficient squared, $\widehat{f}_{I \rightarrow z}(S)^2$, is at most $I_S[f]$; also, the degree of a random restriction (roughly speaking) of $f^{\leq d}$ is significantly smaller than d . Thus, by first applying a random restriction, and then using inequality 3 (the “KKL bound”), one may expect to get a meaningful bound for the second question above — this is indeed the case. An important technical point is that one may “switch” the order of maximum and expectation in this argument, which is where Lemma 3.5 comes in handy.

The above argument gives a stronger bound than inequality (3), provided all of the generalized influence of f (of some order) are very small; this is very much analogous to the KKL Theorem we started with! Again, the following question arises: can we base on this result a similar bound to inequality (3) in case we know f only has a few noticeable generalized influences? This is next step in the argument, and is established in a similar manner to the way we established inequality (3).

The final statement, Theorem 4.1 below, is the outcome of applying this idea inductively. There are several technical points omitted from the above description that need to be taken into account to make it precise. To get a strong enough statement, the set of live variables I should be chosen randomly, but at the same time the degree of $f^{\leq d}$ under random restrictions has to decrease. While this can probably be done, it is likely to be messy, and we bypass it by using random-partitions from Section 3.1. We then discard from the Fourier expansion of $f^{\leq d}$ characters S that remain large with respect to one of the parts (and argue they do not contribute too much to $\langle f, f^{\leq d} \rangle$). Note that after discarding, it will no longer be true that we are working with a function and its low degree part, so to facilitate induction we work with the two-function version of the problem instead. We then look at each part I_j of the partition \mathcal{I} , consider random restrictions of the discarded version of the low-degree part of f and apply the induction hypothesis on them (note that these restrictions also decrease the degree of the function considerably, as the partition \mathcal{I} is picked according to Corollary 3.4). A slightly more detailed overview of the inductive step is given in Section 4.4.

4.2 Statement of the main technical result

In this section, we prove our main technical result. In the following statement, we have $\varepsilon > 0$, and an increasing sequence of integers d_0, \dots, d_k , and we will be interested in S that are of size d_k within factor α ; it will be convenient for us to write it more succinctly as $|S| \sim d_k$.

⁴Namely, the attempt is to run the proof of the KKL theorem with the generalized derivatives instead of standard derivatives. This fails since the sum of the generalized derivatives in general may be much higher than the total influence: if we consider say, order v derivatives, then a character S would be counted by $\binom{|S|}{v}$ generalized influences.

In the statement below, one should think of g (roughly) as $f^{\leq d}$, and the goal is to prove that if f has no large Fourier coefficients, then $\langle f, g \rangle = o(\|f\|_2^2)$, hence f is concentrated on high degrees and in particular $I[f] \geq (1 - o(1))d\|f\|_2^2$. The more general statement with general g is crucial for the inductive proof to go through (as hinted in the overview above).

Theorem 4.1. *Let $k \in \mathbb{N}$, $\alpha, \varepsilon \in (0, 1)$, let d_0, d_1, \dots, d_k be an increasing sequence such that $d_0 = 1$ and for each $3 \leq j \leq k$ we have $d_{j-1} \geq \frac{3}{\alpha\varepsilon^2(1-2\varepsilon)^k} \log(4(1+\varepsilon)d_j/d_{j-1})$, and let $0 < \delta_k \leq \dots \leq \delta_1$. Then there are C_1, C_2, C_3 specified below, such that the following holds.*

If $f: \{0, 1\}^n \rightarrow \{0, 1\}$ is a Boolean function, and $g: \{0, 1\}^n \rightarrow \mathbb{R}$ is (α, d_k) -almost-homogenous, then

$$\langle f, g \rangle \leq C_1 \cdot \max_{|S| \sim d_k} \left| \widehat{f}(S) \widehat{g}(S) \right| + C_2 \cdot I[f, g] + C_3 \cdot \|g\|_2 \|f\|_2. \quad (4)$$

$$C_1 = 2^k d_k^{(1+\varepsilon)d_k} \left(\frac{2}{\delta_k} \right)^{\frac{(1+\varepsilon)d_k}{d_{k-1}}}, \quad C_2 = 2^k \delta_1^{\frac{1}{8}} 3^{\frac{d_1}{4}}, \quad C_3 = 2^k (1+\varepsilon)^k d_k \sum_{j=1}^{k-1} d_j^{(1+\varepsilon)d_j} \left(\frac{2}{\delta_j} \right)^{\frac{(1+\varepsilon)d_j}{d_{j-1}}} \sqrt{3}^{d_{j+1}} \delta_{j+1}^{\frac{1}{4}}.$$

The amount of parameters in the above statement, as well as the formulas for C_1, C_2, C_3 , make the above statement incomprehensible; this form is very convenient for the inductive proof to go through. Once it has been established, one can make a particular choice of the parameters that is typically useful, yielding the following corollary.

Corollary 4.2. *Let $\alpha \in (0, 1)$, $\varepsilon \in (0, 1/2)$ and let $d \in \mathbb{N}$, $\delta > 0$ be such that $d^\varepsilon \geq \frac{100}{\alpha\varepsilon} \log d$ and $\delta \leq 2^{-4d^\varepsilon}$. If $f: \{0, 1\}^n \rightarrow \{0, 1\}$ is a Boolean function, and $g: \{0, 1\}^n \rightarrow \mathbb{R}$ is (α, d) -almost-homogenous, then*

$$\langle f, g \rangle \leq \delta^{-2^{O(1/\varepsilon)d}} \cdot \max_{|S| \sim d} \left| \widehat{f}(S) \widehat{g}(S) \right| + 2^{O(1/\varepsilon)} \delta^{1/40} \cdot I[f, g] + 2^{O(1/\varepsilon)} \delta^{d^\varepsilon} \cdot \|g\|_2 \|f\|_2.$$

Proof. Assume $1/\varepsilon$ is an integer (otherwise we may replace ε with some ε' such that $\varepsilon \leq \varepsilon' \leq 2\varepsilon$ for which $1/\varepsilon'$ is an integer), and set $k = \frac{1}{\varepsilon}$. Choose $d_j = d^{j/k}$ for all $i = 0, 1, \dots, k$, and note that by the lower bound on d , we have $d_{j-1} \geq \frac{3}{\alpha\varepsilon^2(1-2\varepsilon)^k} \log(4(1+\varepsilon)d_j/d_{j-1})$ for all $j \geq 3$. Next, we choose $\delta_1 = \delta$ and $\delta_{j+1} = \delta_j^{80d^\varepsilon}$ for all $j \geq 1$. We apply Theorem 4.1 with these parameters to upper bound $\langle f, g \rangle$, and get that $\langle f, g \rangle \leq C_1 \max_{|S| \sim d_k} \left| \widehat{f}(S) \widehat{g}(S) \right| + C_2 \cdot I[f, g] + C_3 \cdot \|g\|_2 \|f\|_2$ for C_1, C_2, C_3 as in the statement of Theorem 4.1, and next we give simpler upper bounds on C_1, C_2, C_3 for our specific choice of parameters.

Unraveling the definition of δ_{j+1} , we see that $\delta_{j+1} = \delta^{(80d^\varepsilon)^j}$, therefore $C_1 \leq d^{O(d)} \delta^{-\exp(O(1/\varepsilon)d)}$, and since $\delta \leq 2^{-d^\varepsilon} \leq 2^{-\log d} = 1/d$, we get that the $d^{O(d)}$ factor can be absorbed into the second factor. For C_2 , we see that $C_2 \leq 2^{O(1/\varepsilon)} \delta^{1/8} 3^{d^\varepsilon/4} \leq 2^{O(1/\varepsilon)} \delta^{1/40}$ using the upper bound on δ . Finally, for C_3 , consider the j th summand; note that $d_j^{d_j} \leq 2^{d_j \log d} \leq 2^{d_j d^\varepsilon} = 2^{d_{j+1}}$, and that $\delta_{j+1}^{1/4} \leq \delta_j^{20d^\varepsilon}$. Thus,

$$C_3 \leq 2^k (1+\varepsilon)^k d \sum_{j=1}^{k-1} 12^{d_{j+1}} \delta_j^{16d^\varepsilon} \leq 2^k (1+\varepsilon)^k d \sum_{j=1}^{k-1} 12^{d^{(j+1)\varepsilon}} \delta^{16d^j} \leq 2^k (1+\varepsilon)^k d \sum_{j=1}^{k-1} \delta^{8d^j},$$

where in the last inequality we used the fact that $\delta \leq 2^{-d^\varepsilon}$. We bound the sum by k times the maximum summand and get that $C_3 \leq 2^{O(1/\varepsilon)} d \delta^{8d^\varepsilon} \leq 2^{O(1/\varepsilon)} \delta^{d^\varepsilon}$. □

4.3 Base case

The base case $k = 1$ of Theorem 4.1 is an easy consequence of Lemma 4.3 below.

Lemma 4.3. *Let $f: \{0, 1\}^n \rightarrow \{0, 1\}$ be a Boolean function and let $g: \{0, 1\}^n \rightarrow \mathbb{R}$ be of degree at most d . Then for all $\delta > 0$ we have that*

$$\langle f, g \rangle \leq \left(\frac{d}{\delta}\right)^d \max_S \left| \widehat{f}(S)\widehat{g}(S) \right| + 2 \cdot \delta^{1/8} 3^{d/4} I[f, g].$$

Proof. Note that without loss of generality, we may assume that for every S , the signs of the coefficients of S in f and g are the same: indeed, for any other S we may change the sign of $\widehat{g}(S)$, leave the right hand side unchanged and only increase the left hand side (as evident from Parseval/ Plancherel).

Denote by $\text{Inf}[f]$ the set of variables i such that $I_i[f^{\leq d}] \geq \delta$. Writing $\langle f, g \rangle = \sum_S \widehat{f}(S)\widehat{g}(S)$, we partition the sum on the right hand side to $S \subseteq \text{Inf}[f]$ (i.e. only contain variables with high low-degree influence), and the rest. Clearly, we have

$$\langle f, g \rangle = \sum_S \widehat{f}(S)\widehat{g}(S) \leq \underbrace{\sum_{S \subseteq \text{Inf}[f]} \widehat{f}(S)\widehat{g}(S)}_{(I)} + \sum_{i \notin \text{Inf}[f]} \underbrace{\sum_{S \ni i} \widehat{f}(S)\widehat{g}(S)}_{(II)}.$$

Note that $|\text{Inf}[f]| \leq \frac{d}{\delta}$, so the total number of summands in (I) is at most $\left(\frac{d}{\delta}\right)^d$, and we get that

$$(I) \leq \left(\frac{d}{\delta}\right)^d \max_S \widehat{f}(S)\widehat{g}(S).$$

We now proceed to upper bound (II) for each i separately. Fix $i \notin \text{Inf}[f]$. Since the sum is only supported on S of size at most d , we may replace $\widehat{f}(S)$ in that sum with $\widehat{f^{\leq d}}(S)$ and not change it. Hence, we get that

$$(II) = \langle \partial_i f^{\leq d}, \partial_i g \rangle,$$

and using the Cauchy-Schwarz inequality (II) is upper bounded by $\|\partial_i f^{\leq d}\|_2 \|\partial_i g\|_2$. We wish to upper bound the first multiplicand further, and for that we note that $\|\partial_i f^{\leq d}\|_2^2 = \langle \partial_i f^{\leq d}, \partial_i f^{\leq d} \rangle = \langle \partial_i f^{\leq d}, \partial_i f \rangle$ and then use Hölder's inequality with powers $(4, 4/3)$ to get that

$$\langle \partial_i f^{\leq d}, \partial_i f \rangle \leq \|\partial_i f^{\leq d}\|_4 \|\partial_i f\|_{4/3} \leq \sqrt{3}^d \|\partial_i f^{\leq d}\|_2 \|\partial_i f\|_{4/3},$$

where in the last inequality we used Theorem 2.8. Since $i \notin \text{Inf}[f]$, we have that $\|\partial_i f^{\leq d}\|_2 \leq \delta^{1/4} \cdot \|\partial_i f^{\leq d}\|_2^{1/2}$, which by Parseval is at most $\delta^{1/4} \cdot I_i[f]^{1/4}$. To upper bound $\|\partial_i f\|_{4/3}$, as $\partial_i f$ is $\{0, 1/2, -1/2\}$ -valued, we have that $\|\partial_i f\|_{4/3} \leq 2I_i[f]^{3/4}$. Combining the two bounds and taking square root, we get that $\|\partial_i f^{\leq d}\|_2 \leq 2 \cdot 3^{d/4} \delta^{1/8} I_i[f]^{1/2}$, and therefore $(II) \leq 2 \cdot 3^{d/4} \delta^{1/8} \|\partial_i f\|_2 \|\partial_i g\|_2$. \square

4.4 Proof of inductive step

In this section, we prove Theorem 4.1 by induction on k . The base case $k = 1$ follows from Lemma 4.3, noting that since in our case g is (α, d_1) -almost-homogenous, the maximum could be restricted to $|S| \sim d_1$.

Let $k > 1$, assume the statement holds for all $j < k$ and prove it for k . To simplify notation, we recall that by $|S| \sim d_k$ we mean that $\alpha d_k \leq |S| \leq d_k$; also, for $j \leq k - 1$, we say that $|S| \sim d_j$ if $(1 - 2\varepsilon)\alpha d_j \leq |S| \leq d_j$.

Proof overview of the inductive step. Let f, g be functions as in the statement of the theorem, and consider a partition $\mathcal{I} = (I_1, \dots, I_m)$ into $m = d_k/d_{k-1}$ parts as in Lemma 3.3; this partition could be thought of as random. We discard from g characters χ_S for which $|S \cap I_j| \gg d_{k-1}$ for some $j \in [m]$. Thus, thinking of g as a function of only one of the parts, say I_j , its degree is at most d_{k-1} . Our goal is to charge S 's that contribute to $\langle f, g \rangle = \sum_S \widehat{f}(S) \widehat{g}(S)$ to the various random restrictions $f_{\bar{I}_j \rightarrow z}, g_{\bar{I}_j \rightarrow z}$ for $j \in [m]$, where z is a random setting outside the coordinates of I_j , and bound the contribution to the random restrictions using the induction hypothesis.

As hinted earlier, if all of the generalized influences of g corresponding to subsets of I_j are small, then the induction hypothesis allows us to establish a good bound on $\langle f, g \rangle$ by writing it as $\mathbb{E}_z \left[\langle f_{\bar{I}_j \rightarrow z}, g_{\bar{I}_j \rightarrow z} \rangle \right]$. To see that, we focus on the most problematic term that arises from the induction hypothesis involving the maximum over Fourier coefficients (the rest are significantly easier to handle), i.e.

$$\mathbb{E}_{z \in \{0,1\}^{\bar{I}_j}} \left[\max_S \left| \widehat{f_{\bar{I}_j \rightarrow z}}(S) \widehat{g_{\bar{I}_j \rightarrow z}}(S) \right| \right].$$

To prove a good upper bound on this term, one uses Cauchy-Schwarz and then Lemma 3.5 to exchange the maximum and expectation, which results in a bound depending on the generalized influences of g .

However, g could of course have large generalized influences on I_j . Thus, we take g_j to be the part of the Fourier transform of g that consists only of characters χ_S for which $S \cap I_j$ has small generalized influences (if for some S we have that $S \cap I_j$ is non-influential for more than a single j , we choose one such j arbitrary and include χ_S in g_j). Thus, we are able to upper bound $\langle f, g_j \rangle$ successfully using the above strategy. Subsequently we can decompose g as $\sum_{j \in [m]} g_j + E$, where E consists of characters χ_S for which $S \cap I_j$ is influential for all $j \in [m]$. The task then amounts to upper bounding $\langle f, E \rangle$, and for that we use the crude upper bound $\left| \text{supp}(\widehat{E}) \right| \max_S \left| \widehat{f}(S) \widehat{E}(S) \right|$, which is sufficient (using Fact 2.4 to upper bound the size of the support of \widehat{E}).

We now move on to the formal proof.

Formal proof. As before, we may assume without loss of generality that for all Fourier coefficients S , the signs of $\widehat{f}(S)$ and $\widehat{g}(S)$ are the same.

Using Corollary 3.4 with $m = (1+\varepsilon)\frac{d_k}{d_{k-1}}$, $d = d_k$, α and ε we may find a partition \mathcal{I} as in the corollary; let $G(\mathcal{I})$ be the set of all $S \subseteq [n]$ such that for all $j \in [m]$, $S \cap I_j$ is of size $(1+\varepsilon)d_k/m = d_{k-1}$ within factor $(1-2\varepsilon)\alpha$.

Define $\tilde{g}: \{0,1\}^n \rightarrow \mathbb{R}$ by $\tilde{g} = \sum_{S \in G(\mathcal{I})} \widehat{g}(S) \chi_S$. In terms of \tilde{g} , Corollary 3.4 amounts to saying that

$$\langle f, \tilde{g} \rangle \geq \left(1 - 2me^{-\frac{\varepsilon^2 \alpha d}{3m}} \right) \langle f, g \rangle,$$

and by the condition relating d_k and d_{k-1} we get that the factor on the right hand side is at least $\frac{1}{2}$, and therefore $\langle f, g \rangle \leq 2\langle f, \tilde{g} \rangle$ so it is enough to upper bound the inner product of f and \tilde{g} .

Let \mathcal{T} be the set of $T \subseteq [n]$ of size d_{k-1} within factor $(1-\varepsilon)\alpha$ that have large generalized influence in \tilde{g} , i.e. such that $I_T[\tilde{g}] \geq \delta_k \|\tilde{g}\|_2^2$. Since \tilde{g} has degree at most d_k , by Fact 2.4 we get that

$$\sum_{|T| \sim d_{k-1}} I_T[\tilde{g}] \leq \sum_{|T| \leq d_{k-1}} I_T[\tilde{g}] \leq 2d_k^{d_{k-1}} \|g\|_2^2,$$

hence $|\mathcal{T}| \leq \frac{2d_k^{d_k-1}}{\delta_k}$. Writing $\langle f, \tilde{g} \rangle = \sum_S \widehat{f}(S)\widehat{\tilde{g}}(S)$, we partition the sum on the right hand side into two parts: (I) those S that satisfy that $S \cap I_j$ is in \mathcal{T} for all $j \in [m]$, and (II) those S such that $S \cap I_j$ is not in \mathcal{T} for some $j \in [m]$. Denote by \mathcal{S}_j the set of S such that $S \cap I_j \notin \mathcal{T}$, and by \mathcal{B} the set of S that are outside $\mathcal{S}_1 \cup \dots \cup \mathcal{S}_m$. Then we have

$$\langle f, \tilde{g} \rangle \leq \underbrace{\sum_{S \in \mathcal{B}} \widehat{f}(S)\widehat{\tilde{g}}(S)}_{(I)} + \underbrace{\sum_{j=1}^m \sum_{S \in \mathcal{S}_j} \widehat{f}(S)\widehat{\tilde{g}}(S)}_{(II)}, \quad (5)$$

and we upper bound each sum separately.

Upper bounding (I). Clearly, (I) is at most $|\mathcal{B}| \cdot \max_{|S| \sim d_k} \widehat{f}(S)\widehat{\tilde{g}}(S)$ (as the sum is only supported on $|S| \sim d_k$ by the condition on g). To bound the size of \mathcal{B} , note that the map $S \rightarrow (S \cap I_1, \dots, S \cap I_m)$ is a bijection from \mathcal{B} to \mathcal{T}^m , hence we have that

$$|\mathcal{B}| \leq |\mathcal{T}|^m \leq \left(\frac{2d_k^{d_k-1}}{\delta_k} \right)^m = d_k^{(1+\varepsilon)d_k} \left(\frac{2}{\delta_k} \right)^{\frac{(1+\varepsilon)d_k}{d_k-1}} \leq \frac{1}{2} C_1(k).$$

Therefore, the contribution from (I) is upper bounded by the first term on the right hand side in (4). Thus, to complete the proof, it is enough to upper bound the contribution from (II) by the other two terms in the right hand side of (4), and to do so we use the induction hypothesis.

Upper bounding (II). We upper bound the sum corresponding to each $j \in [m]$ separately. Fix j , write $J = \cup_{j' \neq j} I_{j'}$, and $\tilde{g}_j = \sum_{S \in \mathcal{S}_j} \widehat{\tilde{g}}(S)\chi_S$. Note that

$$\mathbb{E}_z [\langle f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z} \rangle] = \langle f, \tilde{g}_j \rangle = \sum_{S \in \mathcal{S}_j} \widehat{f}(S)\widehat{\tilde{g}}(S),$$

and therefore to upper bound (II) it is enough to upper bound the inner product of random restrictions of f and \tilde{g}_j on J . We note that the important point here is that these restrictions lower the degree of \tilde{g}_j from $\sim d_k$ to $\sim d_{k-1}$ (since it is only supported on S such that $|S \cap I_j| \sim d_{k-1}$), and hence we expect to get useful information from the inductive hypothesis on these restrictions.

More precisely, note that for every $z \in \{0, 1\}^J$ the function $f_{J \rightarrow z}$ is Boolean and the function $(\tilde{g}_j)_{J \rightarrow z}$ is $((1 - 2\varepsilon)\alpha, d_{k-1})$ -approximately homogenous. Therefore, we may apply the induction hypothesis with parameters $k - 1, (1 - 2\varepsilon)\alpha, \varepsilon, d_0, \dots, d_{k-1}$ and $\delta_{k-1}, \dots, \delta_1$ on these functions, to get that

$$\begin{aligned} \langle f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z} \rangle &\leq C_1(k-1) \underbrace{\max_{|S| \sim d_{k-1}} \left| \widehat{f_{J \rightarrow z}}(S) \right| \left| \widehat{(\tilde{g}_j)_{J \rightarrow z}}(S) \right|}_{(III)} + C_2(k-1) \underbrace{I[f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z}]}_{(IV)} \\ &\quad + C_3(k-1) \underbrace{\|(\tilde{g}_j)_{J \rightarrow z}\|_2 \|f_{J \rightarrow z}\|_2}_{(V)}. \end{aligned} \quad (6)$$

Here again, we denote

$$C_1(r) = 2^r \cdot d_r^{(1+\varepsilon)d_r} \left(\frac{2}{\delta_r} \right)^{\frac{(1+\varepsilon)d_r}{d_r-1}}, \quad C_2(r) = 2^r \cdot \delta_1^{\frac{1}{8}} 3^{\frac{d_1}{4}},$$

$$C_3(r) = 2^r (1+\varepsilon)^r d_r \sum_{\ell=1}^{r-1} d_\ell^{(1+\varepsilon)d_\ell} \left(\frac{2}{\delta_\ell} \right)^{\frac{(1+\varepsilon)d_\ell}{d_\ell-1}} \sqrt{3}^{d_{\ell+1}} \delta_{\ell+1}^{\frac{1}{4}},$$

and we wish to upper bound the expectation of the left hand side. We bound each one of them separately.

Upper bounding the contribution of (V). By Cauchy-Schwarz we have that

$$\mathbb{E}_z[(V)] = \mathbb{E}_z[\|\tilde{g}_j\|_{J \rightarrow z} \|f_{J \rightarrow z}\|_2] \leq \sqrt{\mathbb{E}_z[\|\tilde{g}_j\|_{J \rightarrow z}^2] \mathbb{E}_z[\|f_{J \rightarrow z}\|_2^2]} = \|\tilde{g}_j\|_2 \|f\|_2 \leq \|g\|_2 \|f\|_2.$$

Upper bounding the contribution of (IV). Using Lemma 2.6, we have that

$$\mathbb{E}_z[(IV)] = \mathbb{E}_z[I[f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z}]] \leq \sum_{i \notin J} I_i[f, \tilde{g}_j] \leq \sum_{i \in I_j} I_i[f, g],$$

where we used the fact that $I_i[\tilde{g}_j] \leq I_i[g]$ (that follows from Parseval's equality).

Upper bounding the contribution of (III). To upper bound the expectation of (III), we first use Cauchy-Schwarz inequality to see that

$$\mathbb{E}_z[(III)] \leq \sqrt{\mathbb{E}_z \left[\max_{|S| \sim d_{k-1}} \widehat{f_{J \rightarrow z}(S)^2} \right]} \sqrt{\mathbb{E}_z \left[\max_{|S| \sim d_{k-1}} \widehat{(\tilde{g}_j)_{J \rightarrow z}(S)^2} \right]}.$$

For each z and each $|S| \sim d_{k-1}$, by Parseval we have that $\widehat{f_{J \rightarrow z}(S)^2} \leq \|f_{J \rightarrow z}\|_2^2$, hence, the first multiplicand is bounded by $\|f\|_2$.

For the second multiplicand we appeal to Lemma 3.5: let us think of the indices therein as being subsets S , and define $h_S(z) = \widehat{(\tilde{g}_j)_{J \rightarrow z}(S)}$; note that since g is of degree at most d_k , we get that each h_S also has degree at most d_k . Thus, applying Lemma 3.5 we get that

$$\mathbb{E}_z \left[\max_S h_S(z)^2 \right] \leq 3^{d_k} \max_S \|h_S\|_2 \left(\mathbb{E}_z \left[\sum_S h_S(z)^2 \right] \right)^{1/2}.$$

Note that by Parseval,

$$\mathbb{E}_z \left[\sum_S h_S(z)^2 \right] = \mathbb{E}_z [\|(\tilde{g}_j)_{J \rightarrow z}\|_2^2] = \|\tilde{g}_j\|_2^2 \leq \|g\|_2^2,$$

and therefore we conclude that $\mathbb{E}_\alpha[(III)] \leq \sqrt{3}^{d_k} \|g\|_2^{1/2} \|f\|_2 \max_S \|h_S\|_2^{1/2}$. Fix S that attains this maximum; using Lemma 2.7, we see that $\|h_S\|_2^2 = \sum_{T: T \cap I_j = S} \widehat{g}_j(T)^2$. Note that if $S \in \mathcal{T}$, then the above sum would be empty (since we do not include a character T in \tilde{g}_j if $T \cap I_j$ has large generalized influence in g), and the sum would be 0. Hence we may assume that $S \notin \mathcal{T}$, and therefore this sum is at most $I_S[g] \leq \delta_k \|g\|_2^2$. Combining, we get that $\mathbb{E}_\alpha[(III)] \leq \sqrt{3}^{d_k} \delta_k^{1/4} \|g\|_2 \|f\|_2$.

Combining the bounds for (III), (IV), (V). Plugging the bounds into (6) and summing over $j \in [m]$, we get that

$$(II) = \sum_{j=1}^m \mathbb{E}_z [\langle f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z} \rangle] \leq m \cdot C_1(k-1) \sqrt{3}^{d_k} \delta_k^{1/4} \|g\|_2 + C_2(k-1) I[f, g] + m \cdot C_3(k-1) \|g\|_2 \|f\|_2.$$

Consider the first and the third terms on the right hand side. Note that

$$m \cdot C_1(k-1) \sqrt{3}^{d_k} \delta_k^{1/4} + m \cdot C_3(k-1) \leq \frac{1}{2} C_3(k),$$

as well as that $C_2(k-1) = \frac{1}{2} C_2(k)$. Therefore the above inequality implies that $(II) \leq \frac{1}{2} C_2(k) I[f, g] + \frac{1}{2} C_3(k) \|g\|_2 \|f\|_2$. Plugging this, as well as the bound we have on (I), into (5), we get that

$$\langle f, \tilde{g} \rangle \leq \frac{1}{2} C_1(k) \max_{|S| \sim d_k} \widehat{f}(S) \widehat{g}(S) + \frac{1}{2} C_2(k) I[f, g] + \frac{1}{2} C_3(k) \|g\|_2 \|f\|_2,$$

and since $\langle f, g \rangle \leq 2 \langle f, \tilde{g} \rangle$, the proof of the inductive step is complete. \square

5 Improving the result

In this section, we prove quantitatively stronger forms of Theorem 4.1 and Corollary 4.2. We will assume some familiarity with the material presented in Sections 3, and 4 and encourage the reader to go over them before proceeding to the current section.

5.1 A variant of Lemma 3.5

We begin by proving the following variant of Lemma 3.5, which is the source of the improvement. The set-up one should have in mind is the following: we have a Boolean function f (whose degree is not necessarily small), a low-degree function g , and a set of variables $J \subseteq [n]$. The functions h_i are the Fourier coefficients of $g_{J \rightarrow x}$, and the functions h'_i are Fourier coefficients of $f_{J \rightarrow x}$. I.e. we think of the indices i as subsets $S \subseteq J$, and have $h_S(z) = \widehat{g_{J \rightarrow z}}(S)$, $h'_S(z) = \widehat{f_{J \rightarrow z}}(S)$. We remark that h_S play the same role as in Lemma 3.5, whereas h'_S did not appear there.

Lemma 5.1. *Let $d \in \mathbb{N}$. Let $h_1, h_2, \dots, h_k: \{0, 1\}^n \rightarrow \mathbb{R}$ be of degree at most d , and $h'_1, \dots, h'_k: \{0, 1\}^n \rightarrow \mathbb{R}$. Then*

$$\mathbb{E}_x \left[\left(\sum_{i=1}^k |h'_i(x)|^{4/3} |h_i(x)|^{4/3} \right)^{3/4} \right] \leq 3^d \max_i (\|h_i\|_2 \|h'_i\|_2)^{1/4} \cdot \left(\mathbb{E}_x \left[\sum_{i=1}^k h'_i(x)^2 \right] \mathbb{E}_x \left[\sum_{i=1}^k h_i(x)^2 \right] \right)^{3/8}.$$

Proof. By Jensen's inequality, the left hand side is at most

$$\left(\mathbb{E}_x \left[\sum_{i=1}^k |h'_i(x)|^{4/3} |h_i(x)|^{4/3} \right] \right)^{3/4} = \left(\sum_{i=1}^k \mathbb{E}_x \left[|h'_i(x)|^{4/3} |h_i(x)|^{4/3} \right] \right)^{3/4}. \quad (7)$$

By Hölder's inequality, we have that

$$\mathbb{E}_x \left[|h'_i(x)|^{4/3} |h_i(x)|^{4/3} \right] \leq \mathbb{E}_x \left[h'_i(x)^2 \right]^{2/3} \mathbb{E}_x \left[h_i(x)^4 \right]^{1/3} = \|h'_i\|_2^{4/3} \|h_i\|_4^{4/3},$$

Using Theorem 2.8 we have $\|h_i\|_4 \leq 3^{d/2} \|h_i\|_2$. Thus, we get that

$$\mathbb{E}_x \left[|h'_i(x)|^{\frac{4}{3}} |h_i(x)|^{\frac{4}{3}} \right] \leq 3^d \|h_i\|_2^{\frac{4}{3}} \|h'_i\|_2^{\frac{4}{3}},$$

and plugging this into (7) yields that

$$(7) \leq 3^d \left(\sum_{i \in [k]} \|h_i\|_2^{\frac{4}{3}} \|h'_i\|_2^{\frac{4}{3}} \right)^{\frac{3}{4}} \leq 3^d \max_i (\|h_i\|_2 \|h'_i\|_2)^{\frac{1}{4}} \left(\sum_{i \in [k]} \|h_i\|_2 \|h'_i\|_2 \right)^{\frac{3}{4}},$$

The result now follows from the Cauchy-Schwarz inequality. \square

5.2 The improved statement

The following statement is an improved form of Theorem 4.1. Specifically the bound we have on C_1 and C_3 is much better. Roughly speaking, the most costly terms in C_3 are $(2/\delta_j)^{(1+\varepsilon)d_j/4d_{j-1}}$, so to make it small one must choose $\delta_{j+1} \sim \delta_j^{(1+\varepsilon)^3 d_j/d_{j-1}}$. This should be compared to Theorem 4.1, in which we are forced to pick $\delta_{j+1} \sim \delta_j^{4d_j/d_{j-1}}$ if we want C_3 to be small; this factor of 4 in the exponent quickly blows up and becomes exponential in k , which forces us to take moderate k since otherwise C_1 would be large.

Theorem 5.2. *Let $k \in \mathbb{N}$, $\alpha, \varepsilon \in (0, 1)$, let d_0, d_1, \dots, d_k be an increasing sequence such that $d_0 = 1$ and for each $2 \leq j \leq k$ we have $d_{j-1} \geq \frac{3}{\alpha \varepsilon^2 (1-2\varepsilon)^k} \log(4(1+\varepsilon)d_j/d_{j-1})$, and let $0 < \delta_k \leq \dots \leq \delta_1$. Then there are C_1, C_2, C_3 specified below, such that the following holds.*

If $f: \{0, 1\}^n \rightarrow \{0, 1\}$ is a Boolean function, and $g: \{0, 1\}^n \rightarrow \mathbb{R}$ is (α, d_k) -almost-homogenous, then

$$\langle f, g \rangle \leq C_1 \cdot \left(\sum_{|S| \sim d_k} |\widehat{f}(S)|^{\frac{4}{3}} |\widehat{g}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}} + C_2 \cdot I[f, g] + C_3 \cdot \|g\|_2 \|f\|_2. \quad (8)$$

For $k = 1$, we have $C_1 = \left(\frac{d_1}{\delta_1}\right)^{\frac{1}{4}d_1}$, $C_2 = 2 \cdot \delta_1^{\frac{1}{8}} 3^{\frac{d_1}{4}}$ and $C_3 = 0$. For $k > 1$, we have $C_1 = 2^k \left(\frac{2}{\delta_k}\right)^{\frac{1+\varepsilon}{4} \frac{d_k}{d_{k-1}}}$, $C_2 = 2^k \delta_1^{\frac{1}{8}} 3^{\frac{d_1}{4}}$, and $C_3 = 2^k (1+\varepsilon)^k d_k \left(\left(\frac{d_1}{\delta_1}\right)^{\frac{1}{4}d_1} \delta_2^{\frac{1}{4}} + \sum_{j=2}^{k-1} \left(\frac{2}{\delta_j}\right)^{\frac{1+\varepsilon}{4} \frac{d_j}{d_{j-1}}} 3^{d_{j+1}} \delta_{j+1}^{\frac{1}{4}} \right)$.

As before, the complicated-looking form of the statement stems from the inductive proof. Later, we pick a convenient setting of the parameters in Corollary 5.4, from which the improvement over Corollary 4.2 is more apparent.

5.2.1 Base case

The base case $k = 1$ of Theorem 5.2 is an easy consequence of Lemma 5.3 below.

Lemma 5.3. *Let $f: \{0, 1\}^n \rightarrow \{0, 1\}$ be a Boolean function and let $g: \{0, 1\}^n \rightarrow \mathbb{R}$ be of degree at most d . Then for all $\delta > 0$ we have that*

$$\langle f, g \rangle \leq \left(\frac{d}{\delta}\right)^{\frac{1}{4}d} \left(\sum_S |\widehat{f}(S)|^{\frac{4}{3}} |\widehat{g}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}} + 2 \cdot \delta^{1/8} 3^{d/4} I[f, g].$$

Proof. Note that without loss of generality, we may assume that for every S , the signs of the coefficients of S in f and g are the same: indeed, for any other S we may change the sign of $\widehat{g}(S)$, leave the right hand side unchanged and only increase the left hand side (as evident from Parseval/ Plancherel).

Denote by $\text{Inf}[f]$ the set of variables i such that $I_i[f^{\leq d}] \geq \delta$. Writing $\langle f, g \rangle = \sum_S \widehat{f}(S)\widehat{g}(S)$, we partition the sum on the right hand side to $S \subseteq \text{Inf}[f]$ (i.e. only contain variables with high low-degree influence), and the rest. Clearly, we have

$$\langle f, g \rangle = \sum_S \widehat{f}(S)\widehat{g}(S) \leq \underbrace{\sum_{S \subseteq \text{Inf}[f]} \widehat{f}(S)\widehat{g}(S)}_{(I)} + \sum_{i \notin \text{Inf}[f]} \underbrace{\sum_{S \ni i} \widehat{f}(S)\widehat{g}(S)}_{(II)}.$$

Note that $|\text{Inf}[f]| \leq \frac{d}{\delta}$, so the total number of summands in (I) is at most $(\frac{d}{\delta})^d$, and we get by Hölder's inequality that

$$(I) \leq \left(\frac{d}{\delta}\right)^{\frac{d}{4}} \left(\sum_S |\widehat{f}(S)|^{\frac{4}{3}} |\widehat{g}(S)|^{\frac{4}{3}}\right)^{\frac{3}{4}}.$$

The bound on (II) is identical to the bound on (II) in the proof of Lemma 4.3. \square

5.2.2 Proof of inductive step

Let $k > 1$, assume the statement holds for all $j < k$ and prove it for k . To simplify notation, we recall that by $|S| \sim d_k$ we mean that $\alpha d_k \leq |S| \leq d_k$; also, for $j \leq k-1$, we say that $|S| \sim d_j$ if $(1-2\varepsilon)\alpha d_j \leq |S| \leq d_j$.

The proof below is the same as the proof in Section 4.4 with two modifications: we sieve out the g to get the functions \tilde{g}_j more carefully so as to make sure the generalized influences of g as well as of f arising in the argument would be small, and use Lemma 5.1 instead of Lemma 3.5.

Proof. As before, by flipping signs of the Fourier coefficients of g if necessary, we may assume without loss of generality that for all S , the signs of $\widehat{f}(S)$ and $\widehat{g}(S)$ are the same.

Using Corollary 3.4 with $m = (1+\varepsilon)\frac{d_k}{d_{k-1}}$, $d = d_k$, α and ε we may find a partition \mathcal{I} as in the corollary; let $G(\mathcal{I})$ be the set of all $S \subseteq [n]$ such that for all $j \in [m]$, $S \cap I_j$ is of size $(1+\varepsilon)d_k/m = d_{k-1}$ within factor $(1-2\varepsilon)\alpha$.

Define $\tilde{g}: \{0, 1\}^n \rightarrow \mathbb{R}$ by $\tilde{g} = \sum_{S \in G(\mathcal{I})} \widehat{g}(S)\chi_S$. In terms of \tilde{g} , Corollary 3.4 amounts to saying that

$$\langle f, \tilde{g} \rangle \geq \left(1 - 2me^{-\frac{\varepsilon^2 \alpha d}{3m}}\right) \langle f, g \rangle,$$

and by the condition relating d_k and d_{k-1} we get that the factor on the right hand side is at least $\frac{1}{2}$, and therefore $\langle f, g \rangle \leq 2\langle f, \tilde{g} \rangle$ so it is enough to upper bound the inner product of f and \tilde{g} .

For each $j \in [m]$ and $T \subseteq I_j$, denote $I_{T, I_j}[\tilde{g}] \stackrel{\text{def}}{=} \sum_{S: S \cap I_j = T} \widehat{\tilde{g}}(S)^2$, and similarly define $I_{T, I_j}[f] \stackrel{\text{def}}{=} \sum_{S: S \cap I_j = T} \widehat{f}(S)^2$. Let \mathcal{T}_j be the collection of all sets $T \subseteq I_j$ such either $I_{T, I_j}[f] \geq \delta_k \|f\|_2^2$ or $I_{T, I_j}[\tilde{g}] \geq \delta_k \|\tilde{g}\|_2^2$. Note that

$$\sum_{T \subseteq I_j} I_{T, I_j}[\tilde{g}] = \sum_S \tilde{g}^2(S) = \|\tilde{g}\|_2^2,$$

hence \tilde{g} contributes at most $1/\delta_k$ sets T to \mathcal{T}_j ; similarly, f also contributes at most $1/\delta_k$ sets T to \mathcal{T}_j , and hence $|\mathcal{T}_j| \leq \frac{2}{\delta_k}$. Writing $\langle f, \tilde{g} \rangle = \sum_S \widehat{f}(S) \widehat{\tilde{g}}(S)$, we partition the sum on the right hand side into two parts: (I) those S that satisfy that $S \cap I_j$ is in \mathcal{T}_j for all $j \in [m]$, and (II) those S such that $S \cap I_j$ is not in \mathcal{T}_j for some $j \in [m]$. Denote by \mathcal{S}_j the set of S such that $S \cap I_j \notin \mathcal{T}_j$, and by \mathcal{B} the set of S that are outside $\mathcal{S}_1 \cup \dots \cup \mathcal{S}_m$. Then we have

$$\langle f, \tilde{g} \rangle \leq \underbrace{\sum_{S \in \mathcal{B}} \widehat{f}(S) \widehat{\tilde{g}}(S)}_{(I)} + \underbrace{\sum_{j=1}^m \sum_{S \in \mathcal{S}_j} \widehat{f}(S) \widehat{\tilde{g}}(S)}_{(II)}, \quad (9)$$

and we upper bound each sum separately.

Upper bounding (I). Note that since g is almost homogenous, we get that (I) is only supported on $|S| \sim d_k$. Therefore, using Hölder's inequality, (I) is at most $|\mathcal{B}|^{\frac{1}{4}} \cdot \left(\sum_{|S| \sim d_k} |\widehat{f}(S)|^{\frac{4}{3}} |\widehat{\tilde{g}}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}}$. To bound the size of \mathcal{B} , note that the map $S \rightarrow (S \cap I_1, \dots, S \cap I_m)$ is a bijection from \mathcal{B} to $\mathcal{T}_1 \times \dots \times \mathcal{T}_m$, hence we have that

$$|\mathcal{B}|^{\frac{1}{4}} \leq \left(\prod_{i=1}^m |\mathcal{T}_i| \right)^{\frac{1}{4}} = \left(\frac{2}{\delta_k} \right)^{m \cdot \frac{1}{4}} = \left(\frac{2}{\delta_k} \right)^{\frac{1+\varepsilon}{4} \frac{d_k}{d_{k-1}}} \leq \frac{1}{2} C_1(k).$$

Therefore, the contribution from (I) is upper bounded by the first term on the right hand side in (15). Thus, to complete the proof, it is enough to upper bound the contribution from (II) by the other two terms in the right hand side of (15), and to do so we use the induction hypothesis.

Upper bounding (II). We upper bound the sum corresponding to each $j \in [m]$ separately. Fix j , write $J = \cup_{j' \neq j} I_{j'}$, and $\tilde{g}_j = \sum_{S \in \mathcal{S}_j} \widehat{\tilde{g}}(S) \chi_S$. Note that

$$\mathbb{E}_z [\langle f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z} \rangle] = \langle f, \tilde{g}_j \rangle = \sum_{S \in \mathcal{S}_j} \widehat{f}(S) \widehat{\tilde{g}}(S),$$

and therefore to upper bound (II) it is enough to upper bound the inner product of random restrictions of f and \tilde{g}_j on J . We note that the important point here is that these restrictions lower the degree of \tilde{g}_j from $\sim d_k$ to $\sim d_{k-1}$ (since it is only supported on S such that $|S \cap I_j| \sim d_{k-1}$), and hence we expect to get useful information from the inductive hypothesis on these restrictions.

More precisely, note that for every $z \in \{0, 1\}^J$ the function $f_{J \rightarrow z}$ is Boolean and the function $(\tilde{g}_j)_{J \rightarrow z}$ is $((1 - 2\varepsilon)\alpha, d_{k-1})$ -approximately homogenous. Therefore, we may apply the induction hypothesis with parameters $k - 1, (1 - 2\varepsilon)\alpha, \varepsilon, d_0, \dots, d_{k-1}$ and $\delta_{k-1}, \dots, \delta_1$ on these functions, to get that

$$\begin{aligned} \langle f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z} \rangle &\leq C_1(k-1) \underbrace{\left(\sum_{|S| \sim d_{k-1}} |\widehat{f_{J \rightarrow z}}(S)|^{\frac{4}{3}} |(\widehat{(\tilde{g}_j)_{J \rightarrow z}}(S))|^{\frac{4}{3}} \right)^{\frac{3}{4}}}_{(III)} + C_2(k-1) \underbrace{I[f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z}]}_{(IV)} \\ &\quad + C_3(k-1) \underbrace{\|(\tilde{g}_j)_{J \rightarrow z}\|_2 \|f_{J \rightarrow z}\|_2}_{(V)}. \end{aligned} \quad (10)$$

Here again, we denote $C_1(k-1), C_2(k-1), C_3(k-1)$ the expressions from Theorem 15 when k is replaced by $k-1$, and we wish to upper bound the expectation of the left hand side. We bound the expectation of each term separately.

Upper bounding the contribution of (V). By Cauchy-Schwarz we have

$$\mathbb{E}_z[(V)] = \mathbb{E}_z[\|(\tilde{g}_j)_{J \rightarrow z}\|_2 \|f_{J \rightarrow z}\|_2] \leq \sqrt{\mathbb{E}_z[\|(\tilde{g}_j)_{J \rightarrow z}\|_2^2] \mathbb{E}_z[\|f_{J \rightarrow z}\|_2^2]},$$

which is equal to $\|\tilde{g}\|_2 \|f\|_2 \leq \|g\|_2 \|f\|_2$.

Upper bounding the contribution of (IV). Using Lemma 2.6, we have that

$$\mathbb{E}_z[(IV)] = \mathbb{E}_z[I[f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z}]] \leq \sum_{i \notin J} I_i[f, \tilde{g}_j] \leq \sum_{i \in I_j} I_i[f, g],$$

where we used the fact that $I_i[\tilde{g}_j] \leq I_i[g]$ (that follows from Parseval's equality).

Upper bounding the contribution of (III). We use Lemma 5.1 to upper bound the expectation of (III). Let us think of the indices therein as being subsets S , and define $h'_S(z) = \widehat{f_{J \rightarrow z}}(S)$ as well as $h_S(z) = \widehat{(\tilde{g}_j)_{J \rightarrow z}}(S)$. Since \tilde{g}_j is of degree at most d_k , we get that h_S is of degree at most d_k .

By Lemma 5.1 we get that

$$\mathbb{E}_z \left[\left(\sum_{|S| \sim d_{k-1}} |h_S(z)|^{\frac{4}{3}} |h'_S(z)|^{\frac{4}{3}} \right)^{\frac{3}{4}} \right] \leq 3^{d_k} \max_{|S| \sim d_{k-1}} (\|h_S\|_2 \|h'_S\|_2)^{\frac{1}{4}} \cdot \left(\mathbb{E}_z \left[\sum_S h'_S(z)^2 \right] \mathbb{E}_z \left[\sum_S h_S(z)^2 \right] \right)^{\frac{3}{8}}.$$

Note that by Parseval,

$$\mathbb{E}_z \left[\sum_S h_S(z)^2 \right] = \mathbb{E}_z [\|(\tilde{g}_j)_{J \rightarrow z}\|_2^2] = \|\tilde{g}_j\|_2^2 \leq \|g\|_2^2,$$

and similarly $\mathbb{E}_z \left[\sum_S h'_S(z)^2 \right] \leq \|f\|_2^2$. Therefore we conclude that

$$\mathbb{E}_z[(III)] \leq 3^{d_k} \max_{|S| \sim d_{k-1}} (\|h_S\|_2 \|h'_S\|_2)^{\frac{1}{4}} (\|f\|_2 \|g\|_2)^{\frac{3}{4}}.$$

Fix S that attains this maximum; using Lemma 2.7, we see that $\|h_S\|_2^2 = \sum_{T: T \cap I_j = S} \widehat{g}_j(T)^2$, which is the same as $I_{S, I_j}[\tilde{g}]$. Note that if $S \in \mathcal{T}_j$, then the above sum would be empty (since we do not include a character T in \tilde{g}_j if $T \cap I_j \in \mathcal{T}_j$), and therefore its value would be 0. Hence we may assume that $S \notin \mathcal{T}_j$, and thus we get that $I_{S, I_j}[\tilde{g}] \leq \delta_k \|g\|_2^2$ and $I_{S, I_j}[f] \leq \delta_k \|f\|_2^2$. Combining, we get that

$$\mathbb{E}_z[(III)] \leq 3^{d_k} \delta_k^{\frac{1}{4}} \|g\|_2 \|f\|_2.$$

Combining the bounds for (III), (IV), (V). Plugging the bounds into (10) and summing over $j \in [m]$, we get that

$$(II) = \sum_{j=1}^m \mathbb{E}_z [\langle f_{J \rightarrow z}, (\tilde{g}_j)_{J \rightarrow z} \rangle] \leq m \cdot C_1(k-1) 3^{d_k} \delta_k^{\frac{1}{4}} \|g\|_2 \|f\|_2 \\ + C_2(k-1) I[f, g] + m \cdot C_3(k-1) \|g\|_2 \|f\|_2. \quad (11)$$

Consider the first and the third terms on the right hand side. Note that

$$m \cdot C_1(k-1) 3^{d_k} \delta_k^{\frac{1}{4}} + m \cdot C_3(k-1) \leq \frac{1}{2} C_3(k),$$

as well as that $C_2(k-1) = \frac{1}{2} C_2(k)$. Therefore the above inequality implies that

$$(II) \leq \frac{1}{2} C_2(k) I[f, g] + \frac{1}{2} C_3(k) \|g\|_2 \|f\|_2.$$

Plugging this, as well as the bound we have on (I), into (9), we get that

$$\langle f, \tilde{g} \rangle \leq \frac{1}{2} C_1(k) \left(\sum_{|S| \sim d_k} |\hat{f}(S)|^{\frac{4}{3}} |\hat{g}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}} + \frac{1}{2} C_2(k) I[f, g] + \frac{1}{2} C_3(k) \|g\|_2 \|f\|_2,$$

and since $\langle f, g \rangle \leq 2 \langle f, \tilde{g} \rangle$, the proof of the inductive step is complete. \square

5.3 A convenient setting of the parameters

Corollary 5.4. Let $\alpha \in (0, 1)$, $\varepsilon \in (0, 1/2)$ and let $d \in \mathbb{N}$, $\delta > 0$ be such that $d^\varepsilon \geq \frac{100}{\alpha \varepsilon} \log d$ and $\delta \leq 2^{-\frac{16}{\varepsilon} d^\varepsilon}$. If $f: \{0, 1\}^n \rightarrow \{0, 1\}$ is a Boolean function, and $g: \{0, 1\}^n \rightarrow \mathbb{R}$ is (α, d) -almost-homogenous, then

$$\langle f, g \rangle \leq \delta^{-6d} \cdot \|f\|_2^{\frac{3}{4}} \|g\|_2^{\frac{3}{4}} \cdot \max_{|S| \sim d} |\hat{f}(S) \hat{g}(S)|^{\frac{1}{4}} + \delta^{1/16} \cdot I[f, g] + \delta \cdot \|f\|_2 \|g\|_2.$$

Proof. Assume $1/\varepsilon$ is an integer (otherwise we may replace ε with some ε' such that $\varepsilon \leq \varepsilon' \leq 2\varepsilon$ for which $1/\varepsilon'$ is an integer), and set $k = \frac{1}{\varepsilon}$. Choose $d_j = d^{j/k}$ for all $j = 0, 1, \dots, k$, and note that by the lower bound on d , we have $d_{j-1} \geq \frac{3}{\alpha \varepsilon^2 (1-2\varepsilon)^k} \log(4(1+\varepsilon)d_j/d_{j-1})$ for all $j \geq 2$. Next, we choose $\delta_1 = \delta$ and $\delta_{j+1} = \delta_j^{(1+\varepsilon)^{2d^\varepsilon}}$ for all $j \geq 1$. We apply Theorem 5.2 with these parameters to upper bound $\langle f, g \rangle$, and get that

$$\langle f, g \rangle \leq C_1 \left(\sum_{|S| \sim d_k} |\hat{f}(S)|^{\frac{4}{3}} |\hat{g}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}} + C_2 \cdot I[f, g] + C_3 \cdot \|g\|_2 \|f\|_2$$

for C_1, C_2, C_3 as in the statement of Theorem 5.2. For the first term observe that

$$\sum_{|S| \sim d_k} |\hat{f}(S) \hat{g}(S)|^{\frac{4}{3}} \leq \max_{|S| \sim d} |\hat{f}(S) \hat{g}(S)|^{\frac{1}{3}} \sum_{|S| \sim d} |\hat{f}(S) \hat{g}(S)| \leq \max_{|S| \sim d} |\hat{f}(S) \hat{g}(S)|^{\frac{1}{3}} \sqrt{\sum_S \hat{f}(S)^2 \sum_S \hat{g}(S)^2},$$

where the last inequality is by Cauchy-Schwarz. By Parseval, this is equal to $\max_{|S| \sim d} |\hat{f}(S) \hat{g}(S)|^{\frac{1}{3}} \|f\|_2 \|g\|_2$.

Next, we give simpler upper bounds on C_1, C_2, C_3 for our specific choice of parameters.

Unraveling the definition of δ_{j+1} , we see that $\delta_{j+1} = \delta^{(1+\varepsilon)^{2j} d^{j\varepsilon}}$, therefore $C_1 \leq 2^k \cdot 2^{d^\varepsilon} \cdot \delta^{-\frac{1}{2}(1+\varepsilon)^{2k}d}$, and since $k = \frac{1}{\varepsilon}$, we get that the $(1+\varepsilon)^{2k} \leq e^2 \leq 9$; using that and the fact that $2^{d^\varepsilon} \leq \delta^{-d/2}$ we conclude that $C_1 \leq 2^k \delta^{-5d} \leq \delta^{-6d}$, where in the last inequality we used $\delta^{-1} \geq 2^{d^\varepsilon} \geq 2^{1/\varepsilon} = 2^k$.

Claim 5.5. $C_3 \leq \delta$.

Proof. We upper bound each one of the summands in the definition of C_3 separately. Fix $2 \leq j \leq k-1$; by the definition of δ_{j+1} we have have that the j th summand is

$$\left(\frac{2}{\delta_j}\right)^{\frac{1+\varepsilon}{4}d^\varepsilon} 3^{d_{j+1}} \delta_{j+1}^{\frac{1}{4}} = \left(\frac{2}{\delta_j}\right)^{\frac{1+\varepsilon}{4}d^\varepsilon} 3^{d_{j+1}} \delta_j^{\frac{(1+\varepsilon)^2}{4}d^\varepsilon} \leq 6^{d_{j+1}} \delta_j^{\frac{\varepsilon}{4}d^\varepsilon} \leq 6^{d_{j+1}} \delta^{\frac{\varepsilon}{4}d^{j\varepsilon}}.$$

Since $d_{j+1} = d^{(j+1)\varepsilon}$ and by the upper bound we have on δ , we get that this is at most $\delta^{\frac{\varepsilon}{16}d^{j\varepsilon}} \leq \delta^2$, where we used $\varepsilon d^{j\varepsilon} \geq \varepsilon d^\varepsilon \geq 100$.

For $j = 1$, the corresponding summand is

$$\left(\frac{d^\varepsilon}{\delta_1}\right)^{\frac{1}{4}d^\varepsilon} \delta_2^{\frac{1}{4}} = \frac{d^{\frac{1}{4}\varepsilon d^\varepsilon}}{\delta_1^{\frac{1}{4}d^\varepsilon}} \delta_1^{\frac{(1+\varepsilon)^2}{4}d^\varepsilon} \leq d^{\frac{1}{2}\varepsilon d^\varepsilon} \delta^{\frac{1}{2}\varepsilon d^\varepsilon} = (d\delta)^{\frac{1}{2}\varepsilon d^\varepsilon} \leq \delta^{\frac{1}{4}\varepsilon d^\varepsilon} \leq \delta^2.$$

In the fourth transition, we used the upper bound on δ and the lower bound on d^ε that imply $\delta \leq 2^{-d^\varepsilon} \leq 2^{-100 \log d} = d^{-100}$, and in particular $d\delta \leq \delta^{1/2}$. In the last transition we used $\varepsilon d^\varepsilon \geq 100$.

Combining the bounds for all j 's we get that $C_3 \leq 2^k (1+\varepsilon)^k d \cdot k \cdot \delta^2$. Now, to see that this is at most δ simply note that $(1+\varepsilon)^k \leq e$ and $\delta \leq 2^{-8d^\varepsilon} \leq 2^{-8 \log d / \varepsilon} \leq \frac{\varepsilon 2^{-1/\varepsilon}}{e \cdot d} = \frac{2^{-k}}{k \cdot e \cdot d}$. \square

Finally, for C_2 note that $3^{d_1/4} \leq 2^{d^\varepsilon/2}$, $2^k \leq 2^{d^\varepsilon}$ and $\delta_1^{1/16} \leq 2^{-d^\varepsilon/\varepsilon} \leq 2^{-2d^\varepsilon}$, and so $C_2 \leq \delta^{1/16}$. \square

6 A further improvement of the result

Corollary 5.4 from the last section can be used to established a quantitatively weaker forms of Theorems 1.1, 1.2 and 1.3, where the logarithmic factor $\log(1 + \tilde{I}[f])$ is to be replaced by $\text{poly}(\log(1 + \tilde{I}[f]))$ (the proof is similar to the proofs we present in Section 7). In this section, we first explain the reason for this quantitative inefficiency, and then show how to improve on it. The overall idea and technique and very similar to what we have done so far, and we will focus on the places in which the arguments differ.

Let us inspect Corollary 5.4 closely. First, we note that a good way to use this corollary is for example to show that the total mass of f on a given level contributed from small Fourier coefficients, e.g.

$$\sum_{|S|=d} \widehat{f}(S)^2 1_{|\widehat{f}(S)| \leq \xi}$$

for some appropriate ξ , is small. To do that, one defines $g = \sum_{|S|=d} \widehat{f}(S) 1_{|\widehat{f}(S)| \leq \xi} \chi_S$, and notes that the above mass is simply $\langle f, g \rangle$. The goal here to pick as large ξ as possible, while still being to prove that $\langle f, g \rangle$ is small (this type of problem naturally arises when one is trying to upper bound entropies as we will see in Section 7).

We now look more specifically at the conditions of Corollary 5.4 that are assumed for the parameters (these turn out to be the cause of the quantitative inefficiency). First, note the factor δ^{-d} that multiplies the

Fourier coefficients; for the right hand side to be small, the magnitude of the Fourier coefficients must be at least as small as δ^d to cancel that factor, hence to be most effective, we should try to pick as large δ as possible.

One condition in Corollary 5.4 asserts that we must have that $\varepsilon d^\varepsilon \geq \log d$, which implies in particular that $\varepsilon \geq \frac{2 \log \log d - \log \log \log d - 1}{\log d}$. The condition on δ implies that we must have $\delta \leq 2^{-d^\varepsilon/\varepsilon}$. and thinking of $\frac{d^\varepsilon}{\varepsilon}$ as a function of ε , we get that it is increasing on the interval $\varepsilon \in [1/\log d, \infty)$, and by the lower bound we argued for ε it follows that $d^\varepsilon/\varepsilon \geq \Omega(\log^3 d/(\log \log d)^2)$ and hence $\delta \leq 2^{-\Omega(\log^3 d/(\log \log d)^2)}$. In this case, the δ^{-d} factor on the right hand side of Corollary 5.4 is at least $2^{\Omega(d \log^3 d/(\log \log d)^2)}$, and for the Corollary to be useful the Fourier coefficients must be at most inversely small.

In other words, we cannot really say anything about Fourier coefficients of f that are of magnitude more than $2^{-d \log^3 d/(\log \log d)^2}$ except that the sum of their squares is 1. In principle, they alone may already contribute $d \frac{\log^3 d}{(\log \log d)^2}$ entropy, and hence to prove better bounds on the entropy we must be able to strengthen the argument so that it can also handle them.

Towards this end, we first highlight the source of this bottleneck lies in the proof of Theorem 5.2. Roughly speaking, the argument therein does successive degree reduction, which is successful as long as we are not trying to reduce the degree to be too small (this is the reason behind the various requirements on the parameters). When our degree becomes too small, we appeal to the base case, i.e. Lemma 5.3, and this point turns out to be at degree $\text{poly}(\log d)$.

To improve upon this argument, we must be able to reduce the degree down further (and not use the base case directly), and this is the key in the quantitative improvement presented in this section. We show a slightly different way to analyze the degree reduction which on the one hand is more efficient, but on the other hand incurs a more serious multiplicative error term for each iteration. However, since we invoke such iterations only when the degree is already very small, there will be very few of them (roughly $\log \log d$) and hence these additional error terms will be negligible. We also note that we need decrease the degree at each step only by a constant factor as opposed to the setting described above, but this doesn't cause any additional complications.

6.1 Reducing from small degrees to very small degrees using random partitions

Fact 6.1. *Let $0 \leq v \leq d$. Then*

$$\binom{d}{v} \geq \frac{1}{16\sqrt{v}} \frac{d^d}{(d-v)^{d-v} v^v}$$

Proof. By Stirling's approximation, we have that $\sqrt{n} \left(\frac{n}{e}\right)^n \leq n! \leq 4\sqrt{n} \left(\frac{n}{e}\right)^n$, and therefore

$$\binom{d}{v} = \frac{d!}{v!(d-v)!} \geq \frac{\sqrt{d} \left(\frac{d}{e}\right)^d}{16\sqrt{d-v} \left(\frac{d-v}{e}\right)^{d-v} \sqrt{v} \left(\frac{v}{e}\right)^v} \geq \frac{1}{16\sqrt{v}} \frac{d^d}{(d-v)^{d-v} v^v}.$$

□

Fact 6.2. *Let $v < d \leq n$ and suppose v divides d . Let $\mathcal{I} = (I_1, \dots, I_{d/v})$ be a random partition into d/v parts. Then for any $S \subseteq [n]$ of size d it holds that*

$$\Pr_{\mathcal{I}} [|S \cap I_i| = v \forall i] \geq \left(\frac{1}{16\sqrt{v}} \right)^{d/v}.$$

Proof. The proof is by induction on d/v . For $d = v$ the claim is obvious. Fix v , assume the claim holds for all $d' < d$ and prove it for d . Note that

$$\Pr_{\mathcal{I}} [|S \cap I_i| = v \forall i] = \Pr_{I_{d/v}} [|S \cap I_{d/v}| = v] \Pr_{\mathcal{I}} [|S \cap I_i| = v \forall i \mid |S \cap I_{d/v}| = v].$$

For the first term, by direct computation we have that

$$\Pr_{I_{d/v}} [|S \cap I_{d/v}| = v] = \binom{d}{v} \left(1 - \frac{1}{d/v} \right)^{d-v} \left(\frac{1}{d/v} \right)^v = \binom{d}{v} \frac{(d-v)^{d-v} v^v}{d^d},$$

and using Fact 6.1 this is at least $\frac{1}{16\sqrt{v}}$. For the second term, conditioning on $I_{d/v}$ we have that

$$\Pr_{\mathcal{I}} [|S \cap I_i| = v \forall i \mid |S \cap I_{d/v}| = v] = \mathbb{E}_{I_{d/v}: |S \cap I_{d/v}| = v} \left[\Pr_{\mathcal{I}' = (I_1, \dots, I_{d/v-1})} [|S \cap I_i| = v \forall i \mid I_{d/v}] \right],$$

where \mathcal{I}' is a random partition of $[n] \setminus I_{d/v}$ into $d/v - 1$ parts. Therefore, by the induction hypothesis it is at least $\left(\frac{1}{16\sqrt{v}} \right)^{d/v-1}$, and we are done. \square

Equipped with the previous fact, one can deduce the following analog of Corollary 3.4 using the same argument used therein.

Corollary 6.3. *Let $v, d \in \mathbb{N}$, and assume that v divided d . Let $f, g: \{0, 1\}^n \rightarrow \mathbb{R}$ be functions such that g is homogenous of degree d . Then there is a partition $\mathcal{I} = (I_1, \dots, I_{d/v})$ such that*

$$\sum_{\substack{|S|=d \\ |S \cap I_i| = v \forall i}} \left| \widehat{f}(S) \widehat{g}(S) \right| \geq \left(\frac{1}{16\sqrt{v}} \right)^{d/v} \sum_{S \subseteq [n]} \left| \widehat{f}(S) \widehat{g}(S) \right|.$$

6.2 Boosted base case

We can now present a lemma that will be useful for us to make further degree reductions after we have already reached a degree that is not too large.

Lemma 6.4. *Let $e_1 \leq e_2, \dots, e_{k-1} \leq e_k$ be given by $e_i = 10^i$ and $\eta_1 \geq \eta_2 \geq \dots \geq \eta_{k-1} \geq \eta_k > 0$.*

Let $f: \{0, 1\}^n \rightarrow \{0, 1\}$ be a Boolean function and let $g: \{0, 1\}^n \rightarrow \mathbb{R}$ be homogenous of degree e_k . Then

$$\langle f, g \rangle \leq C_1 \left(\sum_{|S|=e_k} \left| \widehat{f}(S) \right|^{\frac{4}{3}} \left| \widehat{g}(S) \right|^{\frac{4}{3}} \right)^{\frac{3}{4}} + C_2 \cdot I[f, g] + C_3 \|f\|_2 \|g\|_2, \quad (12)$$

where C_1, C_2 and C_3 are given as follows. We have $C_1 = 10^k (16\sqrt{e_{k-1}})^{10} \left(\frac{10}{\eta_k} \right)^{5/2}$. For C_2 and C_3 we have that

$$C_2 = 2 \cdot \eta_1^{1/8} 3^{e_1/4} \prod_{i=1}^{k-1} (16\sqrt{e_i})^{10}, \quad C_3 = 10^k \prod_{i=1}^{k-1} (16\sqrt{e_i})^{10} \cdot \sum_{j=1}^{k-1} \left(\frac{10}{\eta_j} \right)^{\frac{5}{2}} 3^{e_{j+1}} \eta_{j+1}^{\frac{1}{4}}.$$

Proof. The base case $k = 1$ is Lemma 5.3. Assume the claim holds for $k - 1$ and prove it for k .

By flipping signs of the Fourier coefficients of g if necessary, we may assume without loss of generality that for all S , the signs of $\widehat{f}(S)$ and $\widehat{g}(S)$ are the same.

Using Corollary 6.3, we may find a partition $\mathcal{I} = (I_1, \dots, I_{10})$ (recall that $e_k/e_{k-1} = 10$) such that for $\tilde{g} = \sum_{\substack{|S|=e_k \\ |S \cap I_i|=e_{k-1} \forall i}} \widehat{g}(S)\chi_S$ we have

$$\langle f, g \rangle \leq (16\sqrt{e_{k-1}})^{10} \langle f, \tilde{g} \rangle. \quad (13)$$

From here, we pretty much repeat the inductive step in the proof of Theorem 5.2. For each $j \in [10]$, and $T \subseteq I_j$, denote $I_{T, I_j}[\tilde{g}] = \sum_{S: S \cap I_j = T} \widehat{\tilde{g}}(S)^2$ and similarly for f . Define \mathcal{T}_j be the set of $T \subseteq I_j$ of size e_{k-1}

such that either $I_{T, I_j}[\tilde{g}] \geq \eta_k \|\tilde{g}\|_2^2$ or $I_{T, I_j}[f] \geq \eta_k \|f\|_2^2$. Then $|\mathcal{T}_j| \leq \frac{2}{\eta_k}$.

Denote by \mathcal{S}_j the set of S of size e_k such that $S \cap I_j \notin \mathcal{T}_j$, and let \mathcal{B} the set of S of size e_k that are outside $\mathcal{T}_1 \cup \dots \cup \mathcal{T}_{10}$. Then we may write that

$$\langle f, \tilde{g} \rangle \leq \underbrace{\sum_{S \in \mathcal{B}} \widehat{f}(S)\widehat{\tilde{g}}(S)}_{(I)} + \sum_{j=1}^{10} \underbrace{\sum_{S \in \mathcal{S}_j} \widehat{f}(S)\widehat{\tilde{g}}(S)}_{(II)}, \quad (14)$$

and we upper bound each sum separately.

Upper bounding (I). Using Hölder's inequality, (I) is at most $|\mathcal{B}|^{\frac{1}{4}} \cdot \left(\sum_{|S|=e_k} |\widehat{f}(S)|^{\frac{4}{3}} |\widehat{\tilde{g}}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}}$. To bound the size of \mathcal{B} , note that the map $S \rightarrow (S \cap I_1, \dots, S \cap I_{10})$ is a bijection from \mathcal{B} to $\mathcal{T}_1 \times \dots \times \mathcal{T}_{10}$, hence we have that

$$|\mathcal{B}|^{\frac{1}{4}} \leq \left(\prod_{i=1}^{10} |\mathcal{T}_i| \right)^{\frac{1}{4}} \leq \left(\frac{2}{\eta_k} \right)^{\frac{5}{2}}$$

Therefore, the contribution from (I) is upper bounded by the first term on the right hand side in (12). Thus, to complete the proof, it is enough to upper bound the contribution from (II) by the other two terms in the right hand side of (12), and to do so we use the induction hypothesis.

Upper bounding (II). Writing $g_j = \sum_{S \in \mathcal{S}_j} \widehat{g}(S)\chi_S$, we note that (II) = $\sum_{j=1}^{10} \langle f, g_j \rangle$, and it suffices to upper bound each one of $\langle f, g_j \rangle$ separately. Fix j and let $J = \bigcup_{i \neq j} I_i$. Then we may write

$$\langle f, g_j \rangle = \mathbb{E}_{z \in \{0,1\}^J} [\langle f_{J \rightarrow z}, (g_j)_{J \rightarrow z} \rangle],$$

and apply the induction hypothesis for each z separately using the parameters $\eta_1, \dots, \eta_{k-1}$ and e_1, \dots, e_{k-1} . We proceed now in the same fashion as in the proof of Theorem 5.2 and get equation (11) therein, i.e.

$$(II) \leq 10 \cdot C_1(k-1)3^{e_k}\eta_k^{1/4} \|g\|_2 \|f\|_2 + C_2(k-1)I[f, g] + 10 \cdot C_3(k-1) \|g\|_2 \|f\|_2$$

Note that the first and third term on the right hand side sum up to at most $\frac{C_3(k)}{(16\sqrt{e_{k-1}})^{10}} \|f\|_2 \|g\|_2$. Thus, plugging this and the bound we have on (I) into equation (14), and then into equation (13), finishes the proof. \square

Corollary 6.5. *Let e' be a power of 10, let $\eta > 0$ be such that $\eta \leq 10^{-320\sqrt{e'}}$. Let $f: \{0, 1\}^n \rightarrow \{0, 1\}$ be a Boolean function and let $g: \{0, 1\}^n \rightarrow \mathbb{R}$ be homogenous of degree e' . Then*

$$\langle f, g \rangle \leq \frac{1}{\eta^{30e'}} \left(\sum_{|S|=e'} |\widehat{f}(S)|^{\frac{4}{3}} |\widehat{g}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}} + \eta^{1/16} \cdot I[f, g] + \eta \|f\|_2 \|g\|_2.$$

Proof. Denote $e' = 10^k$ and set $e_i = 10^i$ for $i = 1, \dots, k$, $\eta_1 = \eta$ and inductively $\eta_{i+1} = \eta_i^{\frac{e_i+1}{e_i} (1+4e_i^{-1/4})}$. We use Lemma 6.4 with these parameters, and upper bound each one of C_1, C_2, C_3 .

For C_1 , by choice of e_{k-1} we have that $C_1 \leq 16^{10} \cdot 10^{6k-5} \left(\frac{10}{\eta_k}\right)^{5/2} \leq 10^{6k+20} \frac{1}{\eta_k^{5/2}}$. By definition, we get that

$$\eta_k = \eta^{e' \prod_{i=1}^{k-1} (1+4e_i^{-1/4})} \geq \eta^{e' \prod_{i=1}^{\infty} (1+4 \cdot 10^{-i/4})} \geq \eta^{29e'},$$

and we also note that $10^{6k+20} \leq \eta^{-e'}$ by the upper bound on η . Hence $C_1 \leq \frac{1}{\eta^{30e'}}$.

For C_2 , we have that

$$C_2 \leq 2\eta_1^{1/8} 3^{10/4} \prod_{i=1}^{k-1} 10^{5i+20} \leq 2\eta^{1/8} 3^{5/2} \cdot 10^{5k^2+20k} \leq 10^{5k^2+30k} \eta^{1/8} \leq \eta^{1/16},$$

where in the last inequality we used the upper bound we have on η .

Finally, for C_3 we first upper bound each summand in the sum individually. Let $1 \leq j \leq k-1$, then $\eta_{j+1} = \eta_j^{10(1+4e_j^{-1/4})}$ and so

$$\left(\frac{10}{\eta_j}\right)^{5/2} 3^{e_{j+1}} \eta_{j+1}^{1/4} = 10^{5/2} \cdot 3^{e_{j+1}} \cdot \eta_j^{\frac{1}{4} \cdot 10 \cdot 4 \cdot e_j^{-1/4}} = 10^{5/2} \cdot 3^{10^{j+1}} \eta^{10^j \cdot 3 \cdot e_j^{-1/4}} \leq \eta^2 \cdot 3^{10^{j+1}} 10^{-320\sqrt{e'} 10^{3j/4}},$$

where we have used the upper bound we have on η . Since $e' = 10^k \geq 10^{j+1}$, we get that

$$3^{10^{j+1}} 10^{-320\sqrt{e'} 10^{3j/4}} \leq 3^{10^{j+1}} 10^{-320 \cdot \sqrt{10^{j+1}} 10^{3j/4}} \leq 1.$$

Therefore, each summand in the definition of C_3 is at most η^2 , and consequently we get that

$$C_3 \leq 10^k \cdot 10^{5k^2+20k} \cdot k \cdot \eta^2 \leq \eta,$$

where in the last inequality we used the upper bound on η again. \square

6.3 Boosted general statement

Theorem 6.6. *Let $k \in \mathbb{N}$, $\alpha \in (0, 1]$, $\varepsilon \in (0, 1/2)$, let $d_0, e' = d_1, \dots, d_k$ be an increasing sequence such that $d_0 = 1$ and for each $2 \leq j \leq k$ we have $d_{j-1} \geq \frac{3}{\alpha \varepsilon^2 (1-2\varepsilon)^k} \log(4(1+\varepsilon)d_j/d_{j-1})$, and let $0 < \delta_k \leq \dots \leq \delta_1 = \eta$. Assume that $\eta \leq 10^{-320 \cdot \sqrt{10e'}}$. Then there are C_1, C_2, C_3 specified below, such that the following holds.*

If $f: \{0, 1\}^n \rightarrow \{0, 1\}$ is a Boolean function, and $g: \{0, 1\}^n \rightarrow \mathbb{R}$ is (α, d_k) -almost-homogenous, then

$$\langle f, g \rangle \leq C_1 \cdot \left(\sum_{|S| \sim d_k} |\widehat{f}(S)|^{\frac{4}{3}} |\widehat{g}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}} + C_2 \cdot I[f, g] + C_3 \cdot \|g\|_2 \|f\|_2. \quad (15)$$

For $k = 1$, we have $C_1 = 10d_1 \frac{1}{\eta^{300e^7}}$, $C_2 = 10d_1 \eta^{1/16}$ and $C_3 = 10d_1 \eta$.

For $k > 1$, we have $C_1 = 2^k \left(\frac{2}{\delta_k} \right)^{\frac{1+\varepsilon}{4} \frac{d_k}{d_{k-1}}}$, $C_2 = 2^k \cdot 100 \cdot d_1^2 \cdot \eta^{1/16}$, and

$$C_3 = 2^k (1 + \varepsilon)^k \left(10d_k \frac{1}{\eta^{300e^7}} \delta_2^{\frac{1}{4}} + \sum_{j=2}^{k-1} \left(\frac{2}{\delta_j} \right)^{\frac{1+\varepsilon}{4} \frac{d_j}{d_{j-1}}} 3^{d_{j+1}} \delta_{j+1}^{\frac{1}{4}} \right).$$

Proof. As before, we may assume the signs of Fourier coefficients of f and g match.

The case $k = 1$. This case is essentially given by Corollary 6.5, except that here we are dealing with almost homogenous g (as opposed to homogenous g) and that e' is not necessarily a power of 10, however both of these issues are very easy to fix.

Since g is (α, d_1) -almost homogenous, it is supported only on characters of size between αd_1 and d_1 , and in particular there exists $\alpha d_1 \leq d' \leq d_1$ such that for $\tilde{g} = \sum_{|S|=d'} \widehat{g}(S) \chi_S$ we have $\langle f, g \rangle \leq d_1 \langle f, \tilde{g} \rangle$.

Next, let $I \subseteq [n]$ be a random subset that contains each $i \in [n]$ independently with probability $1/d'$. Then

$$\mathbb{E}_I \left[\sum_{|S:|S \cap I|=1} \widehat{f}(S) \widehat{g}(S) \right] = \sum_{|S|=d'} \widehat{f}(S) \widehat{g}(S) \Pr_I[|S \cap I| = 1] \geq \frac{1}{10} \sum_{|S|=d'} \widehat{f}(S) \widehat{g}(S) = \frac{1}{10} \langle f, \tilde{g} \rangle.$$

Therefore, defining $\tilde{g}' = \sum_{S:|S \cap I|=1} \widehat{g}(S) \chi_S$ we get that $\langle f, g \rangle \leq d_1 \langle f, \tilde{g} \rangle \leq 10d_1 \langle f, \tilde{g}' \rangle$.

Let h be the closest power of 10 to d' such that $h \geq d'$, and note that $h \leq 10d' \leq 10d_1 = 10e'$. We now may replace each variable x_i for $i \in I$ with $h - d' + 1$ variables $x_{i,1}, \dots, x_{i,h-d'+1}$, substituting each appearances of x_i with $x_{i,1} + \dots + x_{i,h-d'+1}$. Abusing notations, we think of the functions \tilde{f}, \tilde{g}' as being defined over the new variables, we now note that \tilde{g}' has degree $d' - 1 + 1 \cdot (h - d' + 1) = h$ (since each character in \tilde{g}' included one variable from I which was replaced by $h - d' + 1$ variables). We now apply Corollary 6.5 on \tilde{f}, \tilde{g}' , and note that (15) readily follows from it. Indeed, for that we note that $\|\tilde{f}\|_2 = \|f\|_2$, that $\|\tilde{g}'\|_2 \leq \|g\|_2$ and finally that $I[\tilde{f}, \tilde{g}'] \leq h \cdot I[f, g]$.

The inductive step. The inductive step is performed in the same way as in Theorem 5.2, and we omit it. \square

Corollary 6.7. Let $\alpha \in (0, 1], d \in \mathbb{N}$ and $\delta > 0$ be such that $\delta \leq \frac{1}{d^{96000/\sqrt{\alpha}}}$.

If $f: \{0, 1\}^n \rightarrow \{0, 1\}$ is a Boolean function, and $g: \{0, 1\}^n \rightarrow \mathbb{R}$ is (α, d) -almost-homogenous, then

$$\langle f, g \rangle \leq \delta^{-10^5 d} \cdot \|f\|_2^{\frac{3}{4}} \|g\|_2^{\frac{3}{4}} \cdot \max_{|S| \sim d} \left| \widehat{f}(S) \widehat{g}(S) \right|^{\frac{1}{4}} + \delta^{1/16} \cdot I[f, g] + \delta \cdot \|f\|_2 \|g\|_2.$$

Proof. We intend to use Theorem 6.6, and for that we make the choice of parameters.

Set $d_1 = e' = \frac{1000}{\alpha} (\log d)^2$, and note that by the condition on δ , $\delta \leq 10^{-320\sqrt{10e^7}}$. Inductively, set $d_{i+1} = 2d_i$ until we hit $i = k$ such that $2d_i > d$, in which case we set $d_k = d$. Note that clearly, $k \leq \log d$, and denote $\varepsilon = \frac{1}{\log d}$. Note that by the choice of parameters, we have that $d_{j-1} \geq \frac{3}{\alpha \varepsilon^2 (1-2\varepsilon)^k} \log(4(1 + \varepsilon)d_j/d_{j-1})$ for all $j \geq 2$, so the conditions of Theorem 6.6 on the degrees hold, and we next choose $\eta = \delta_1, \dots, \delta_k$.

Choose $\eta = \delta_1 = \delta$, $\delta_2 = \delta_1^{1600d_1}$ and inductively $\delta_{i+1} = \delta_i^{2 \cdot (1+\varepsilon)^2}$ for $i \geq 2$. We note that for $j \leq k-2$ we have $\delta_{j+1} = \delta_2^{(1+\varepsilon)^{2(j-1)} \frac{d_j+1}{d_2}}$, and for $j = k-1$ we have $\delta_2^{(1+\varepsilon)^{2(j-1)} \frac{d_k}{d_2}} \leq \delta_k \leq \delta_2^{(1+\varepsilon)^{2(j-1)} \frac{d_k}{d_2}}$.

We now apply Theorem 6.6 and get that

$$\langle f, g \rangle \leq C_1 \left(\sum_{|S| \sim d_k} |\widehat{f}(S)|^{\frac{4}{3}} |\widehat{g}(S)|^{\frac{4}{3}} \right)^{\frac{3}{4}} + C_2 \cdot I[f, g] + C_3 \cdot \|g\|_2 \|f\|_2,$$

for C_1, C_2, C_3 as in the statement of Theorem 6.6. For the first term observe that

$$\sum_{|S| \sim d_k} |\widehat{f}(S)\widehat{g}(S)|^{\frac{4}{3}} \leq \max_{|S| \sim d} |\widehat{f}(S)\widehat{g}(S)|^{\frac{1}{3}} \sum_{|S| \sim d} |\widehat{f}(S)\widehat{g}(S)| \leq \max_{|S| \sim d} |\widehat{f}(S)\widehat{g}(S)|^{\frac{1}{3}} \sqrt{\sum_S \widehat{f}(S)^2 \sum_S \widehat{g}(S)^2},$$

where the last inequality is by Cauchy-Schwarz. By Parseval, this is equal to $\max_{|S| \sim d} |\widehat{f}(S)\widehat{g}(S)|^{\frac{1}{3}} \|f\|_2 \|g\|_2$.

Next, we calculate upper bounds for C_1, C_2, C_3 for our specific choice of parameters.

We start with C_1 . Since $\delta_k \geq \delta_2^{(1+\varepsilon)^{2(j-1)} \frac{d_k}{d_2}}$ we get that

$$\begin{aligned} C_1 &= 2^k \left(\frac{2}{\delta_k} \right)^{\frac{1+\varepsilon}{4} \frac{d_k}{d_{k-1}}} \leq 2^k \cdot 2^{\frac{1+\varepsilon}{4} \frac{d_k}{d_{k-1}}} \cdot \delta_2^{-\frac{1+\varepsilon}{4} (1+\varepsilon)^{2(k-1)} \cdot 2 \frac{d}{d_2}} \\ &\leq 2^{k+1} \cdot \delta_2^{-10 \frac{d}{d_2}} = 2^{k+1} \cdot \delta^{-16000 \frac{d \cdot d_1}{d_2}} = 2^{k+1} \cdot \delta^{-16000d} \leq \delta^{-10^5 d}, \end{aligned}$$

where in the last inequality we used the upper bound we have on δ and the fact that $k \leq \log d$.

Next, for C_2 we have

$$C_2 = 2^k \cdot 100 \cdot d_1^2 \cdot \eta^{1/16} \leq \delta^{1/32},$$

where we used $k \leq \log d$, $\eta = \delta$ and the upper bound we have on δ .

Finally, for C_3 we upper bound each summand separately. Fix $2 \leq j \leq k-1$; by the definition of δ_{j+1} we have that the j th summand is

$$\left(\frac{2}{\delta_j} \right)^{\frac{1+\varepsilon}{4} \frac{d_{j+1}}{d_j}} 3^{d_{j+1}} \delta_{j+1}^{\frac{1}{4}} \leq \left(\frac{2}{\delta_j} \right)^{\frac{1+\varepsilon}{4} \cdot 2} 3^{d_{j+1}} \delta_j^{\frac{(1+\varepsilon)^2}{4} \cdot 2} \leq 6^{d_{j+1}} \delta_j^{\frac{\varepsilon}{2}} \leq 6^{d_{j+1}} \delta^{120\varepsilon d_j}.$$

Since $\delta \leq \frac{1}{d}$ and $\varepsilon = \frac{1}{\log d}$, we get that $\delta^{60\varepsilon d_j} \leq 2^{-60d_j} \leq 2^{-30d_{j+1}} \leq 6^{-d_{j+1}}$, so that we get that the j th summand is at most $\delta^{60\varepsilon d_j}$. Since $d_j \geq d_1 \geq \log d$, we get that this is at most δ^{60} .

For $j = 1$, the corresponding summand is

$$10d_k \frac{1}{\eta^{300e'}} \delta_2^{\frac{1}{4}} = 10d_k \frac{1}{\eta^{300e'}} \eta^{400e'} = 10d_k \delta^{100e'} \leq \delta^{60}$$

by the upper bound on δ . Combining, we get that

$$C_3 = 2^k (1 + \varepsilon)^k \cdot k \delta^{60} \leq \delta. \quad \square$$

7 Implications of Corollary 6.7

In this section, we deduce from Corollary 6.7 several implications, including Theorems 1.1, 1.2 and 1.3 from the introduction.

7.1 Fourier entropies: proof of Theorem 1.3

We begin by proving Theorem 1.3, restated below.

Theorem 1.3 (Restated) . *There exists an absolute constant $K > 0$, such that for every $D \in \mathbb{N}$ and any $f: \{0, 1\}^n \rightarrow \{0, 1\}$ we have that*

$$H[f^{\widehat{\leq D}}] \leq K \cdot \sum_{|S| \leq D} |S| \log(|S| + 1) \widehat{f}(S)^2 + K \cdot I[f].$$

Proof. We first handle the empty character. By the isoperimetric inequality we conclude

$$I[f] \geq \text{var}(f) \log \left(\frac{1}{\text{var}(f)} \right) = \widehat{f}(\emptyset) (1 - \widehat{f}(\emptyset)) \log \left(\frac{1}{\widehat{f}(\emptyset) (1 - \widehat{f}(\emptyset))} \right) \geq \frac{1}{4} \widehat{f}(\emptyset)^2 \log \left(\frac{1}{\widehat{f}(\emptyset)^2} \right),$$

where in the last inequality we used $z(1-z) \log(1/z(1-z)) \geq \frac{1}{4} z^2 \log(1/z^2)$ that holds for all $z \in [0, 1]$.

For the rest of the proof we assume without loss of generality that $\Pr_x [f(x) = 1] \leq \frac{1}{2}$, since otherwise we may work with the function $1 - f$. For each $1 \leq d \leq D$ and a non-negative integer k , define

$$\mathcal{S}_{d,k} = \left\{ S \mid |S| = d, 2^{-C(k+1) \cdot d \log(d+1)} \text{var}(f)^{1/2} < |\widehat{f}(S)| \leq 2^{-Ck \cdot d \log(d+1)} \text{var}(f)^{1/2} \right\},$$

and $g_{d,k} = \sum_{S \in \mathcal{S}_{d,k}} \widehat{f}(S) \chi_S$. Our main goal will be to bound the inner product $\langle f, g_{d,k} \rangle$, which is equal to the

Fourier mass of f on $\mathcal{S}_{d,k}$. Fix $d \geq 1$ and $k \geq 1$, and set $\delta = \delta(d, k) = 2^{-32k} d^{-10^5}$ and $\alpha = 1$; then by Corollary 6.7 we have, using the upper bound on the Fourier characters, that

$$\langle f, g_{d,k} \rangle \leq \delta^{-10^5} d 2^{-\frac{1}{2} Ck \cdot d \log(d+1)} \cdot 2 \text{var}(f) + \delta^{1/16} I[f, g] + \delta \cdot 2 \text{var}(f). \quad (16)$$

We also used the fact that $\|f\|_2^2, \|g\|_2^2 \leq 2 \text{var}(f)$. Using the definition of δ and the fact that C is large enough, we get that the first term is at most $2^{-\frac{1}{4} Ck \cdot d \log(d+1)} \text{var}(f) \leq 2^{-k} \frac{1}{d^{10}} I[f]$, and the other two terms combined are at most $2^{-k} \frac{1}{d^{10}} I[f]$. Therefore, the contribution of $\mathcal{S}_{d,k}$ to the entropy of f over $d \geq 1$ and $k \geq 1$ is at most

$$\begin{aligned} \sum_{1 \leq d \leq D, k \geq 1} \sum_{S \in \mathcal{S}_{d,k}} \widehat{f}(S)^2 \log \left(\frac{1}{\widehat{f}(S)^2} \right) &\leq \sum_{1 \leq d \leq D, k \geq 1} \langle f, g_{d,k} \rangle \left(2C(k+1) \cdot d \log(d+1) + \log \left(\frac{1}{\text{var}(f)} \right) \right) \\ &\leq \sum_{d,k \geq 1} 2^{2-k} \frac{I[f]}{d^{10}} C(k+1) \cdot d \log(d+1) + \text{var}(f) \log \left(\frac{1}{\text{var}(f)} \right) \\ &\leq O(C \cdot I[f]), \end{aligned}$$

where in the last inequality we used the fact that the sum over k and d is $O(1)$, and the isoperimetric inequality. Lastly, we upper bound the contribution from $\mathcal{S}_{d,0}$ for $d \geq 1$ to the Fourier entropy of f .

$$\begin{aligned} \sum_{1 \leq d \leq D} \sum_{S \in \mathcal{S}_{d,0}} \widehat{f}(S)^2 \log \left(\frac{1}{\widehat{f}(S)^2} \right) &\leq \sum_{1 \leq d \leq D} \sum_{S \in \mathcal{S}_{d,0}} \widehat{f}(S)^2 \cdot \left(2C \cdot d \log(d+1) + \log \left(\frac{1}{\text{var}(f)} \right) \right) \\ &\leq 2C \sum_{1 \leq |S| \leq D} |S| \log(|S| + 1) \widehat{f}(S)^2 + \text{var}(f) \log \left(\frac{1}{\text{var}(f)} \right), \end{aligned}$$

and the second term on the right hand side is upper bounded by $O(I[f])$ using the edge isoperimetric inequality. \square

7.2 Fourier min-entropy: proof of Theorem 1.1

Next, we note that the argument in the proof of Theorem 1.3 implies Theorem 1.1, restated below. Recall that $\tilde{I}[f] = \frac{I[f]}{\text{var}(f)}$.

Theorem 1.1 (Restated) . *There exists an absolute constant $C > 0$, such that for any $f: \{0, 1\}^n \rightarrow \{0, 1\}$ there is a non-empty $S \subseteq [n]$ of size at most $10\tilde{I}[f]$, such that $|\hat{f}(S)| \geq 2^{-C|S|\log(1+\tilde{I}[f])} \sqrt{\text{var}(f)}$.*

Proof. We run the proof of Theorem 1.3 with $D = 10\tilde{I}[f]$ with slight changes. Namely, we take

$$\mathcal{S}_{d,k} = \left\{ S \mid |S| = d, 2^{-C(k+1) \cdot d \log(1+\tilde{I}[f])} \text{var}(f)^{1/2} < |\hat{f}(S)| \leq 2^{-Ck \cdot d \log(1+\tilde{I}[f])} \text{var}(f)^{1/2} \right\},$$

and define $g_{d,k}$ in the same way. Choose $\delta = \delta(d, k) = 2^{-256k} d^{-10^5} \tilde{I}[f]^{-16}$ and $\alpha = 1$. By Corollary 6.7 for each $k \geq 1, d \geq 1$ we have that

$$\langle f, g_{d,k} \rangle \leq \delta^{-10^5} d 2^{-\frac{1}{2} C k \cdot d \log(1+\tilde{I}[f])} \cdot 2 \text{var}(f) + \delta^{1/16} I[f, g] + \delta \cdot 2 \text{var}(f).$$

By choice of parameters, the first term is at most $2^{-4k} \frac{1}{d^2} \text{var}(f)$ given C is sufficiently large constant, and it is easy to see that the other two terms are also at most $2^{-4k} \frac{1}{d^2} \text{var}(f)$. Therefore, we get that $\langle f, g_{d,k} \rangle \leq 3 \cdot 2^{-4k} \frac{1}{d^2} \text{var}(f)$, and so

$$\sum_{k \geq 1, d \geq 1} \langle f, g_{d,k} \rangle \leq 3 \cdot \text{var}(f) \cdot \sum_{d \geq 1} \frac{1}{d^2} \cdot \sum_{k \geq 1} 2^{-4k} \leq 3 \frac{\pi^2}{48} \text{var}(f) \leq 0.7 \text{var}(f).$$

Therefore, $\sum_{d \geq 1} \langle f, g_{d,0} \rangle \geq \text{var}(f) - 0.7 \text{var}(f) = 0.3 \text{var}(f)$. Since by Markov's inequality we have

$$\sum_{d \geq D} \langle f, g_{d,0} \rangle = \sum_{|S| \geq D} \hat{f}(S)^2 \leq 0.1 \text{var}(f),$$

it follows that $\sum_{1 \leq d \leq D} \langle f, g_{d,0} \rangle \geq 0.2 \text{var}(f) > 0$, so there is $d \leq D$ such that $\mathcal{S}_{d,0} \neq \emptyset$, implying there is a character $S \in \mathcal{S}_{d,0}$ as desired. \square

7.3 Fourier concentration: proof of Theorem 1.2

Next, we show that Theorem 1.3 implies Theorem 1.2, restated below.

Theorem 1.2 (Restated) . *For every $\eta > 0$, there exists $C > 0$, such that for all $f: \{0, 1\}^n \rightarrow \{0, 1\}$ we have*

$$\sum_S \hat{f}(S)^2 1_{|\hat{f}(S)| \leq 2^{-C \cdot \tilde{I}[f] \log(1+\tilde{I}[f])}} \leq \eta \cdot \text{var}(f). \quad (17)$$

Proof. By Markov's inequality we have that $\sum_{|S| \geq \frac{2}{\eta} \tilde{I}[f]} \hat{f}(S)^2 \leq \frac{\eta}{2} \text{var}(f)$, therefore it is enough to bound the contribution of $|S| \leq \frac{2}{\eta} \tilde{I}[f]$ to the left hand side of (17) by $\eta/2 \cdot \text{var}(f)$. Choose $D = \frac{2}{\eta} \tilde{I}[f]$; by Theorem 1.3

we get that $H[\widehat{f^{\leq D}}] \leq K(I[f] + I[f] \log D) \leq K'(\eta)I[f] \log(1 + \tilde{I}[f])$, thus

$$\begin{aligned} \sum_{|S| \leq D} \widehat{f}(S)^2 1_{|\widehat{f}(S)| \leq 2^{-C \cdot \tilde{I}[f] \log(1 + \tilde{I}[f])}} &\leq \text{var}(f) \sum_{|S| \leq D} \widehat{f}(S)^2 \frac{\log(1/\widehat{f}(S)^2)}{C \cdot I[f] \log(1 + \tilde{I}[f])} \\ &= \text{var}(f) \frac{H[\widehat{f^{\leq D}}]}{C \cdot I[f] \log(1 + \tilde{I}[f])}, \end{aligned}$$

which is at most $\text{var}(f)K'/C$. Choosing $C = \frac{2}{K'\eta}$ completes the proof. \square

7.4 An application to transitively symmetric functions

In this section, we show how Theorem 1.1 implies an improved form of the Bourgain-Kalai theorem for functions with constant variance.

Let $G \subseteq S_n$ be a subgroup. For each subset $S \subseteq [n]$, the orbit of S under G is $\text{orbit}_G(S) = \{\pi(S) \mid \pi \in G\}$. Define the parameter $a_T(G)$ to be the largest K , such that each S of size at most K has $|\text{orbit}_G(S)| \geq 2^{T|S| \log(K)}$.

Corollary 7.1. *There are $T > 0$ and $c > 0$ such that the following holds. Let $f: \{0, 1\}^n \rightarrow \{0, 1\}$ be a function that is symmetric under an invariant subgroup $G \subseteq S_n$. Then $I[f] \geq c \cdot a_T(G) \text{var}(f)$.*

Proof. Choose $C > 0$ from Theorem 1.1. We prove the statement for $c = \frac{1}{10}$ and $T = 2C$.

Assume towards contradiction that $I[f] < c \cdot a_T(G) \text{var}(f)$; in particular we have $\tilde{I}[f] < a_T(G) - 1$. By Theorem 1.1 there is a non-empty $S \subseteq [n]$ of size at most $10\tilde{I}[f]$ such that $|\widehat{f}(S)| \geq 2^{-C|S| \log(1 + \tilde{I}[f])} \sqrt{\text{var}(f)}$. Fix this S , and note that by symmetry we have that $\widehat{f}(Q) = \widehat{f}(S)$ for all $Q \in \text{orbit}_G(S)$, and hence

$$|\text{orbit}_G(S)| \widehat{f}(S)^2 = \sum_{Q \in \text{orbit}_G(S)} \widehat{f}^2(Q) \leq \text{var}(f),$$

so $|\widehat{f}(S)| \leq \frac{\sqrt{\text{var}(f)}}{\sqrt{|\text{orbit}_G(S)|}}$. Since $|S| \leq 10\tilde{I}[f] \leq a_T(G)$, we get by the definition of $a_T(G)$ that $|\text{orbit}_G(S)| \geq 2^{T|S| \log a_T(G)}$. Combining the lower bound and upper bound on $|\widehat{f}(S)|$ we conclude that $2^{\frac{1}{2}T|S| \log a_T(G)} \leq 2^{C \cdot |S| \log(1 + \tilde{I}[f])}$, which since $T = 2C$ implies that $\tilde{I}[f] \geq a_T(G) - 1$, and contradiction. \square

Implication for graph properties. Suppose f is a graph property with constant variance. In this case, the input is the adjacency vector of length $n = \binom{N}{2}$ of an N -vertex graph, hence f is symmetric under the action of permutations on the vertices, i.e. of S_N . Therefore, the orbit of a collection of $s \leq N$ edges has size at least $\binom{N}{\sqrt{s}} \geq \left(\frac{N}{\sqrt{s}}\right)^{\sqrt{s}} \geq 2^{\frac{1}{2}\sqrt{s} \log N}$. Therefore, if we fix c, T from Corollary 7.1, we see that if $s \leq \left(\frac{\log N}{2T \log \log^2 N}\right)^2$, then the orbit of a collection of any s edges is at least of size $2^{Ts \log(\log^2 N)}$. This implies that

$$a_T(G) \geq \min \left(\log^2 N, \left(\frac{\log N}{2T \log \log^2 N} \right)^2 \right) = \Omega \left(\frac{\log^2 n}{(\log \log n)^2} \right),$$

hence $I[f] = \Omega((\log n)^2 / (\log \log n)^2)$.

Implication for other groups of symmetry. In general, Corollary 7.1 gives better lower bounds on $I[f]$ assuming that f is symmetric under some subgroup G .

For example, if G is S_n or A_n , the orbit of any $S \subseteq [n]$ such that $|S| \leq \sqrt{n}$ has size at least $\binom{n}{|S|/2} \geq n^{c|S|} = 2^{c|S|\log n}$ for some absolute constant c . Therefore by definition $a_T(G) \geq n^{\Omega(1)}$ for any constant T , Corollary 7.1 implies that any f symmetric under G must have at least polynomially large total influence. Using the result of Bourgain and Kalai, the best bound that could be achieved in this case was of the order $2^{\sqrt{\log n}}$.

Acknowledgments

We thank Gil Kalai for valuable conversations over the years and helpful comments. We also thank Yuval Filmus, Nathan Keller and Subhash Khot for comments about an earlier version of this manuscript.
