

A_∞ structures as a language for open Gromov-Witten theory

Short talks by postdoctoral members, IAS, fall 2017

Sara Tukachinsky

Gromov-Witten theory ($g = 0$)

Setting: (X, ω, J) symplectic manifold with almost complex structure

$X = X^{2n}$, ω 2-form such that $\omega^{\wedge n}$ is a volume form

$J \in \text{End}(TX), J^2 = -\text{Id}$, “ ω -tame”

Example: $(\mathbb{C}P^n, \omega_{FS}, J_0)$

Problem: Count J -holomorphic maps from the sphere

$$u: S^2 \rightarrow X$$

that satisfy various constraints

The moduli space of sphere maps

$$\overline{\mathcal{M}}_l(\beta) = \overline{\left\{ \left(u: S^2 \xrightarrow{J\text{-hol.}} X, w_1, \dots, w_l \right) \cdot \begin{array}{l} [u] = \beta \in H_2(X; \mathbb{Z}) \\ w_j \in S^2, w_i \neq w_j \end{array} \right\} / \sim}$$

Compactification:

Rephrasing the problem

Count elements of $\overline{\mathcal{M}}_l(\beta)$ such that the marked points are mapped to given constraints.

Can be expressed as an integral:

$$GW_\beta(\gamma_1, \dots, \gamma_l) = \int_{\overline{\mathcal{M}}_l(\beta)} ev_1^* \gamma_1 \wedge \dots \wedge ev_l^* \gamma_l.$$

Some facts

- GW invariants are defined by the above integral if the space $\overline{\mathcal{M}}_l(\beta)$ is “nice”
- GW are generally hard to compute
- In some cases, can compute GW invariants by the WDVV (Witten-Dijkgraaf-Verlinde-Verlinde) equation

Kontsevich (1994)

degree = d	No. of degree-d curves in $\mathbb{C}P^2$ through $3d-1$ points

Open Gromov-Witten theory ($g = 0$)

Setting: (X, ω, J) symplectic manifold with almost complex structure

$L \subset X$ a Lagrangian submanifold ($\dim L = \frac{1}{2} \dim X, \omega|_L = 0$)

Example: $(X, L, \omega, J) = (\mathbb{C}P^n, \mathbb{R}P^n, \omega_{FS}, J_0)$

Problem: Count J -holomorphic maps from the disk

$$u: (D, \partial D) \rightarrow (X, L)$$

that satisfy various constraints.

The moduli space of disk maps

$$\overline{\mathcal{M}}_{k,l}(\beta) = \overline{\left\{ \left(\begin{array}{l} u: (D, \partial D) \xrightarrow{J\text{-hol.}} (X, L), \\ z_1, \dots, z_k, w_1, \dots, w_l \end{array} \right) \cdot \begin{array}{l} [u] = \beta \in H_2(X, L; \mathbb{Z}) \\ z_i \in \partial D, w_j \in \text{int}(D) \end{array} \right\} / \sim}$$

Compactification:

Rephrasing the problem

Count elements of $\overline{\mathcal{M}}_{k,l}(\beta)$ such that the marked points are mapped to given constraints

Can be expressed as an integral:

$$\begin{aligned} OGW_{\beta}(\alpha_1, \dots, \alpha_k; \gamma_1, \dots, \gamma_l) &= \\ &= \int_{\overline{\mathcal{M}}_{k,l}(\beta)} evb_1^* \alpha_1 \wedge \dots \wedge evb_k^* \alpha_k \wedge evi_1^* \gamma_1 \wedge \dots \wedge evi_l^* \gamma_l. \end{aligned}$$

Issue: $\partial \overline{\mathcal{M}}_{k,l}(\beta) \neq \emptyset$.

Some previous results

OGW are defined when

- S^1 acts on (X, L) (*Liu, 2004*)
- (X, L, ω, J) is a real symplectic manifold with $\dim_{\mathbb{C}} X = 2, 3$, real interior constraints, point boundary constraints (*Cho, Solomon, 2006*)
- (X, L, ω, J) is a real symplectic manifold with $\dim_{\mathbb{C}} X$ odd, no boundary constraints (*Georgieva, 2013*)

OGW are computable via a WDVV-like equation when

- (X, L, ω, J) is a real symplectic manifold with $\dim_{\mathbb{C}} X = 2$, real interior constraints, point boundary constraints (*Horev-Solomon, 2012*)
- (X, L, ω, J) is a real symplectic manifold with $\dim_{\mathbb{C}} X$ odd, no boundary constraints (*Georgieva-Zinger, 2013*)

A_∞ structure

= Algebraic language to describe boundary behavior

- A_∞ operators describe disks with prescribed boundary constraints
- A_∞ relations describe disk bubbling

- Special kind of boundary constraint: “bounding chain”

More results (joint with Jake Solomon)

- OGW can be defined using bounding chains when $\dim_{\mathbb{C}} X$ is odd, under cohomological conditions. E.g., $H^*(L; \mathbb{R}) = H^*(S^n; \mathbb{R})$.
- The boundary constraints can be interpreted as points.
- Whenever defined, OGW satisfy open WDVV equations.
- For $(\mathbb{C}P^n, \mathbb{R}P^n)$, all invariants are determined by the open WDVV.

$$(X, L) = (\mathbb{C}P^n, \mathbb{R}P^n)$$

$$\text{Initial condition: } \mathbf{OGW}_{1,2}^n = \mathbf{2}$$

More questions

- Reduce cohomological assumptions
- Find structure suitable for $g > 0$

- Explore relative quantum cohomology

open WDVV \Leftrightarrow associativity of relative quantum product

Thank you
